A similar tone of high seriousness informs *Daniel Deronda* (1874–6), in which two plots gradually converge, with the initially self-centred Gwendolen Harleth finding sustenance in the moral and emotional values of Judaism, a corpus that offers an alternative to her laissez-faire English upbringing.

Robert Louis Stevenson (1850–94)

The Edinburgh-born Stevenson was one of the most prodigious and eclectic talents of nineteenth-century writing, though he is best remembered as the author of classic children's books and one of the great horror stories of English literature, *The Strange Case of Dr Jekyll and Mr Hyde* (1886). *Treasure Island* (1883) with its boy-narrator Jim Hawkins's story of buried treasure and pirates is both a brilliant piece of children's fiction and a novel that suggests the complexities of "evil", one of Stevenson's recurrent themes, in its representation of the figure of Long John Silver. Earlier R.M. Ballantyne's *The Coral Island* (1871) had made a similar use of an island setting for an adventure story that derives much of its appeal from taking a group of boys into unknown territory.

Stevenson's *Kidnapped* (1886) is a darker tale of dispossession, in which the hero David Balfour suffers at the hands of his cruel Uncle Ebenezer. *Dr Jekyll and Mr Hyde* is a study of a split personality, which among other things reflects Victorian unease about the impact of Darwinian theory on beliefs about identity. Other important novels by Stevenson include the sequel to *Kidnapped*, *Catriona* (1893), *The Black Arrow* (1888) and *The Master of Ballantrae* (1889). Suffering from ill health, he left Britain in 1888 and settled in Samoa, enjoying a new lease of literary life. His writing during his Samoan years, which includes the novellas, *The Beach of Falesá* (1893) and *The Ebb-Tide* (1894), protests against the colonial exploitation of the South Seas.

Schoolboy Fiction, Adventure Stories and the Literature of Empire

Unlike Stevenson, the majority of other Victorian writers of adventure stories can be seen as contributing, intentionally or otherwise, to the late Victorian literature of Empire, often developing links between the values instilled in the English public school and subsequent service in the Empire. Classic schoolboy novels that suggest such connections include Thomas Hughes's *Tom Brown's Schooldays* (1857) and Rudyard Kipling's *Stalky & Co* (1899), which closes with its former schoolboys in India. Such writing was also a staple of popular magazines such as the *Boys Own Paper*, where writers like Talbot Baines Reed, later famed for the classic public school novel, *The Fifth Form at St Dominic's* (serialized in the *Boys Own Paper* in 1907), linked team games and a sporting ethic of fair play with Christian morality and charitable work in the Empire.

Haggard and Henty

Rider Haggard's *King Solomon's Mines* (1885), the story of an expedition to find diamonds in southern Africa and its sequels *Allan Quatermain* (1887) and *She* (1887) are notable among the many adventure novels of the period. The heroic thrust of Haggard's work was sometimes seen as a counterforce to naturalism's more pessimistic view of people's capacity to influence their situation. G.A. Henty's numerous tales of heroic virtue, such as *With Clive in India* (1884) and *With Wolfe in Canada* (1887), characteristically link derring-do, Christianity and Empire. Other romances of the period with "exotic" locations include Anthony Hope Hawkins's *The Prisoner of Zenda* (1894), in which Hope created the mythical European country of Ruritania, and W.H. Hudson's *Green Mansions* (1904), a tale set in the South American rain forest.

Earlier Captain Frederick Marryat's stories of sea adventurers had included *Peter Simple* (1834) and *Mr Midshipman Easy* (1836). John Buchan continued the tradition of adventure writing in the early twentieth century with novels such as *Prester John* (1910) and *The Thirty-Nine Steps* (1915).

Novels of Sensation and Mystery

The Victorian vogue for melodrama, sensation and mystery reached its apogee in the novels of Wilkie Collins, whose *The Woman in White* (1860) demonstrates considerable skill in creating suspense. Collins's *The Moonstone* (1868) laid the groundwork for the modern detective novel, though the American Edgar Allan Poe, had pioneered detective fiction in his short stories about August

Dupin, particularly "Murders in the Rue Morgue" and "The Purloined Letter". Dupin was a forerunner of the most famous detective of the nineteenth century, Sir Arthur Conan's Doyle Sherlock Holmes, whose use of deductive reasoning demonstrated a similar fascination with what Poe termed "ratiocination". At the beginning of the twentieth century, the Catholic convert G.K. Chesterton took the figure in a new direction by relating his detective, Father Brown's skill in solving crimes to his capacity to understand evil.

Sir Arthur Conan Doyle (1859–1930)

Holmes and his omnipresent assistant, Dr Watson first appeared in the novels *A Study in Scarlet* (1887) and *The Sign of Four* (1890), but it was the short stories that Conan Doyle wrote for *The Strand Magazine* in the 1890s that secured his popularity. They were collected in *The Adventures of Sherlock Holmes* (1892) and *The Memoirs of Sherlock Holmes* (1894). Doyle killed Holmes off, when he had him plunge to his death at the Reichenbach Falls in Switzerland in a struggle with his arch-enemy Professor Moriarty, but he was forced to resurrect him in response to public demand. The detective reappeared in several subsequent volumes, including Doyle's best-known work, *The Hound of the Baskervilles* (1902) and the short story collections, *The Return of Sherlock Holmes* (1905) and *The Case-Book of Sherlock Holmes* (1927).

The Gothic Novel

At the end of the nineteenth century, the Gothic novel reached new heights in Bram Stoker's classic vampire novel, *Dracula* (1897). Written as a series of first-person narratives that partly help to authenticate its sensational subject-matter, Stoker's novel drew on pre-existing vampire literature to create the figure of the Transylvanian Count who has become the archetypal vampire of the popular imagination. Contemporary reviewers appear to have been blind to the sexual implications of vampirism, which were to become a major part of the Dracula myth in the film treatments of the twentieth century.

Thomas Hardy (1840–1928)

Often described as England's one major tragic novelist, Hardy set his work in the fictional West Country region of Wessex, based on his native Dorset. It provided him with an environment that was both very specifically localized and a stage for archetypal human dramas. In all his novels, the human action is played out against a vividly realized rural landscape, which can become a character in its own right. *The Return of the Native* (1878) is set against the landscape of Egdon Heath, described at the outset as having "a lonely face, suggesting tragic possibilities". The setting of *The Woodlanders* (1887), Hintock Woods, is similarly crucial to the action, while the experiences of the heroine of *Tess of the D'Urbervilles* (1891) in a number of different landscapes reflect her situation and state of mind at each particular juncture.

The causes of Hardy's tragic protagonists' downfalls vary. Sometimes, as in *The Mayor of Casterbridge* (1886), where he quotes the dictum, "character is fate", they can be attributed to character flaws: Henchard, the mayor of the novel's title, sells his wife, while drunk. Elsewhere, as in *Tess of the D'Urbervilles*, where Hardy writes in the final paragraph "The President of the Immortals, in Aeschylean phrase, had ended his sport with Tess", fate seems the dominant force. At the same time Tess, like several other Hardy characters, is a victim of the moral conventions of her day and throughout his work, Hardy demonstrates an acute sense of the impact of social forces, particularly moral codes and mechanization, on individuals and agrarian communities. His other major novels include *Under the Greenwood Tree* (1872), *Far from the Madding Crowd* (1874), *The Trumpet-Major* (1880) and *Jude the Obscure* (1896).

Later Novels and Poetry

The later novels, *Tess* and *Jude*, are not without melodrama, but the tragic fates of their protagonists suggest the influence of Naturalism and a belief in social determinism. The sub-title of *Tess*, "a pure woman", attracted criticism, since in conventional terms its heroine was a "fallen woman"; and the sympathetic representation of extramarital sexual relations in *Jude the Obscure* evoked a similar response. When a copy of *Jude* was burned by a bishop on the grounds of the novel's supposed obscenity, Hardy forsook fiction and turned to poetry, commenting ruefully, "Nobody will be hurt by my poetry, because nobody will read it".

He wrote verse throughout the remainder of his life. His poetry ranges between simple ballads of folk experience that drew on local Dorset traditions, particularly the work of the Dorset poet, William Barnes, and more personal lyrics, notable among which is a series of elegiac poems written after the death of his wife, Emma, in 1912. These were published in *Satires of Circumstance, Lyrics and Reveries* (1914). His other poetry includes *Wessex Poems and Other Verses* (1898), *Poems of the Past and Present* (1902) and the epic drama, *The Dynasts* (1903–08).

Naturalism in English Fiction

In the latter part of the nineteenth century, the collapse of traditional belief-systems, the influence of Darwinism and a growing awareness of the effect of environment on character led to the rise of the heightened form of social realism known as "Naturalism". Its major theorist was the French novelist Emile Zola and it was never as important a movement in England as in France and the USA, where its practitioners included Stephen Crane, Frank Norris and Theodore Dreiser. Notable English naturalistic novels of the *fin de siècle* years include George Gissing's *New Grub Street* (1891) and George Moore's *Esther Waters* (1894) and its influence is also apparent in the determinism of Hardy's *Tess* and *Jude*.

The continuing, albeit limited, popularity of Naturalism in the early twentieth century can be seen in Arnold Bennett's novels, such as *The Old Wives' Tale* (1908) and *Riceyman Steps* (1923), which provide meticulously detailed, warts-and-all accounts of the lives of ordinary people. However, for Modernist writers such as Virginia Woolf and D.H. Lawrence, Naturalism was a form of fiction that, despite its care in rendering such details, failed to engage with all that was most vital in human experience. Woolf distanced herself from Bennett in her essay "Mr Bennett and Mrs Brown", in which she argued he completely failed to capture the character of people, such as "Mrs Brown", an ordinary woman in a railway carriage. Lawrence referred to Bennett as "an old imitator", commenting scathingly, "Tell Arnold Bennett that all rules of construction hold good only for novels which are copies of other novels".

VICTORIAN LITERATURE

Elizabeth Barrett Browning (1806–61)

Born in England into a plantation-owning Jamaican Creole family, Elizabeth Barrett became a vehement critic of slavery and other social injustices. Sometimes remembered as the wife of Robert Browning, particularly as represented in the film versions of Rudolf Besier's play *The Barretts of Wimpole Street* (1930), she was a major poet in her own right. She was considered a strong candidate for the post of Poet Laureate when Wordsworth died in 1850 and had a greater reputation as a poet than her husband-to-be when they met in 1845.

Her first volume to attract critical favour was *The Seraphim and Other Poems* (1838). A lung condition she first developed as a child, a spinal injury and grief at her brother's death from drowning in 1838 rendered her an invalid and recluse in the house of her domineering father. *Poems* (1844), which included "The Cry of the Children", secured her reputation and led to the beginnings of her correspondence with Browning. After their elopement and marriage, they moved to Florence, where her health improved and she lived for the remainder of her life.

Her *Sonnets from the Portuguese*, which appeared in *Poems* (1850), is a sequence of forty-four love poems written to Browning, which has no connection with any Portuguese originals. It contains her most famous poem, "How do I love thee,/ Let me count the ways". *Aurora Leigh* (1857) is a verse novel, in which she explores a broad range of social issues, including the "Woman Question", the predicament of the poor, child labour and the role of poetry. Her support for Italian unification informs *Casa Guidi Windows* (1851) and *Poems before Congress* (1860). Her *Last Poems* were published posthumously in 1862. Her popularity declined after her death, but the feminist dimension of her work and its engagement with other social and political issues have occasioned a revival of interest in recent decades.

Alfred, Lord Tennyson (1809–92)

Raised in a Lincolnshire rectory, Tennyson attended Cambridge, where he developed a close friendship with Arthur Hugh Hallam, with whom he subsequently travelled in continental Europe. His *Poems, Chiefly Lyrical* (1830), written under the influence of the Romantics, met with little success, but includes a number of poems for which he is remembered, among them "Mariana", "The Palace of Art" and "The Lady of Shalott", his first important poem on an Arthurian subject. *Poems* (1833) includes "The Two Voices" and "The Lotos-Eaters". Hallam had become engaged to Tennyson's sister, Emily, but died suddenly at the age of twenty-two, and the grief-stricken Tennyson commenced the sequence of 131 elegiac poems that would eventually be published as *In Memoriam: A.H.H.* (1850) in 1833. *English Idyls and Other Poems* (1842) contains some of his finest short poems: "Morte d'Arthur", "Ulysses", "Break, break, break" and "Locksley Hall", a disappointed lover's trochaic monologue, which engages with the state of contemporary society.

His Best-Known Lyrics

The Princess (1847) is a long blank verse poem, containing some of Tennyson's best-known lyrics, including "Tears, Idle Tears". Later satirized by Gilbert and Sullivan in their comic-opera *Princess Ida*, it is an incipiently feminist poem: the eponymous heroine rejects her betrothed and founds a university for women. The lovers *are* eventually united, but the romantic resolution is tempered by a passage which looks forward to their married future in which "man be more of woman, she of man". *In Memoriam* begins as a moving expression of personal loss, but expands outwards to encompass a wide range of philosophical and social issues, progressing from a deep sense of doubt to an affirmative conclusion in which new scientific knowledge is reconciled with Biblical teachings. It was published in the year of Wordsworth's death and its immediate popularity was a factor in Tennyson's succeeding him as Poet Laureate.

Tennyson and Queen Victoria

His work was greatly admired by Prince Albert, Queen Victoria's consort, and he became the favourite poet of the Queen herself, who is said to have held his poems second only to the Bible. He eventually accepted a baronetcy from her in 1884. Tennyson's Laureateship led to the writing of poems on such subjects as the death of Wellington (1852), the opening of the International Exhibition of 1862 and, most famously, "The Charge of the Light Brigade" (1854). *Maud* (1855) is a monodrama about a luckless young man, which inveighs against the materialism of the age and contains a number of popular lyrics.

The *Idylls of the King* (1859–85) is a series of twelve poems on the Arthurian legend, which have the encyclopaedic range of epic poetry and include several self-contained narratives, such as that of Geraint and Enid. They were enormously popular in Tennyson's own day, but have been less well regarded by subsequent critics and the consensus of later opinion has been that his greatest gift was as a lyric poet. However, read as an allegory in which the fortunes of Camelot relate to contemporary society, the *Idylls* offer a fascinating exploration of the changing spirit of the age. *Tiresias and Other Poems* (1885) includes "Locksley Hall Sixty Years After", another expression of personal loss that offers a conservative commentary on the state of the nation, as the speaker attacks the dominance of scientific values and the social consequences of industrialization.

Other work from the period of Tennyson's Laureateship includes the highly popular narrative poem, *Enoch Arden* (1864), *Ballads and Other Poems* (1880) and the plays, *Queen Mary* (1875), *The Cup* (1884) and *Becket* (1884). By the time of his death Tennyson was a public institution, but his reputation had dwindled among his younger contemporaries.

Robert Browning (1812–89)

Browning was born into a nonconformist family in South London and was mainly privately educated. His early work was written under the influence of Shelley, and in poems such as *Paracelsus* (1835), a study of the Swiss alchemist, and *Sordello* (1840), in which he took one of Dante's contemporaries as his subject, he combined metaphysical and poetic inquiry with a talent for dramatizing individual psychologies that was to become one of the main characteristics of his subsequent verse.

His greatest achievements were in the form of the dramatic monologue, a genre he made uniquely his own, creating personae with a psychological complexity more normally associated with the novel and rendering them in a range of colloquial and unconventional registers. Most of his finest work in this mode was published in the various parts of *Bells and Pomegranates* (1841–6) and *Men and Women* (1855). It includes "My Last Duchess", "The Bishop Orders His Tomb at St Praxed's Church", "Fra Lippo Lippi", "Bishop Blougram's Apology" and "Andrea del Sarto". His skill as a writer of narrative poems can be seen in "The Pied Piper of Hamelin", "How They Brought the Good News from Ghent to Aix" and "Childe Roland to the Dark Tower Came".

Browning's plays mainly belong to his early period. They include *Pippa Passes* (1841), A *Blot in the 'Scutcheon* (1843) and *Colombe's Birthday* (1844). Some were never intended for performance and generally they show a surer touch in the handling of character than action.

Marriage and Italy

Browning's admiration for Elizabeth Barrett's poetry led him to write to her and they eventually eloped and married in 1846. They settled in Italy, a country which he had first visited in 1838 and which provided the inspiration for many of his most famous works, and lived there until her death in 1861. His "Home Thoughts from Abroad", particularly remembered for its opening "Oh, to be in England/ Now that April's there", was written in Tuscany. The serialized publication of *The Ring and the Book* (1868–9), a poem of more than 20,000 lines, in monthly instalments, secured Browning's reputation with a wider reading public. It tells the story of a seventeenth-century Roman murder from several different viewpoints, once again demonstrating his virtuosity in handling dramatized figures, while also covering an encyclopaedic range of subjects.

During his later years Browning's poetic output continued unabated. Notable works from his last two decades include *Red-Cotton Nightcap Country* (1873), *The Inn Album* (1875), *Dramatic Idyls* (1879–80) and *Asolando* (1889). The foundation of the Browning Society in 1881 reflects the adulation in which he was held by a section of the late Victorian reading public. Along with Tennyson, he was regarded as one of the two pre-eminent poets of the period.

Matthew Arnold (1822–88)

The son of Thomas Arnold, the famous headmaster who made Rugby School a model for nineteenth-century middle-class education, Matthew Arnold was a polymath who took a leading role in many of the cultural debates of the Victorian era and became Professor of Poetry at Oxford in 1858. Today he is best known for his literary criticism and writings on the state of English culture. However, his poetry includes some of the finest nineteenth-century lyrics, among them his "Marguerite" poems and his best-known short poem, "Dover Beach" (1867), a powerful expression of the uncertainties of the age, written in melancholy slow-moving verse. Three longer narrative poems, "Tristram and Iseult" (1852), "Sohrab and Rustum" (1853) and "Balder Dead" (1855) respectively turned to medieval, eastern and Norse mythology for heroic subjects, while treating them in an unconventionally sombre vein. Arnold's elegiac poems include "The Scholar-Gipsy" (1853), which laments the impossibility of a simple pastoral response to landscape in the troubled climate of Victorian doubt, and "Thyrsis" (1867), a monody on the death of his friend, Arthur Hugh Clough. *Empedocles on Etna* (1852) is a verse drama.

Arnold's Literary Criticism

Arnold's literary criticism laid the foundations for the development of the subject along detached and "disinterested" lines and was influential in the construction of English literature as an object of academic study in the late nineteenth and early twentieth century. *Culture and Anarchy* (1869) advanced an idealistic view of culture as a kind of secular religion, seeing it as "the best that has been thought and said in the world", a definition that remained popular until the middle of the twentieth century. Written under the influence of Cardinal Newman, his later writings on the religious controversies of the day, which include *Literature and Dogma* (1873), were an attempt to reconcile rationalism and faith. Arnold saw his work as a response to the main movements of Victorian thought that combined the emotion of Tennyson with the intellect of Browning. In his poem "To a Friend", he said of Sophocles that he "saw life steadily, and saw it whole" and his own response to what he viewed as the "sick disease" of contemporary life can be seen as similarly balanced and harmonious.

The Rossettis and the Pre-Raphaelites

Founded in 1848, the Pre-Raphaelite Brotherhood was a movement in art and literature that rejected the prevalent cultural fashions of the day in favour of a return to what it saw as the simplicity of the medieval era. Its members included Holman Hunt, John Everett Millais and Dante Gabriel Rossetti. While its most significant achievements were in painting, its poetry included noteworthy work by Rossetti, which employed archaic language and mystical symbolism and, with the exception of "Jenny" (1870), a ballad about a London prostitute, found its subjects in medieval, particularly Arthurian, legends.

His best-known poem, "The Blessed Damozel" (1850), reflects an idealized Platonic conception of love and was followed by his later painting of the same theme. Rossetti's sister, Christina, is best known for her collection *Goblin Market and Other Poems* (1862). Contemporary critics have found homoerotic tendencies and a tension between sensuality and renunciation in its title-poem, a gnomic allegory about two sisters who exemplify different aspects of nineteenth-century womanhood. Such a tension is typical of much of her poetry, in which a mystical spiritualism, born out of her high Anglican faith, co-exists with eroticism. Her verse demonstrates considerable technical virtuosity and she was a particularly accomplished writer of sonnets.

Her later collections include *The Prince's Progress and Other Poems* (1866) and *A Pageant and Other Poems* (1881). Several other poets were associated with the Pre-Raphaelites, though they were not members of the original Brotherhood. These included Algernon Charles Swinburne, George Meredith and William Morris.

Gerard Manley Hopkins (1844–89)

Hopkins was a Catholic convert, who was ordained as a Jesuit priest in 1877. An important poetic innovator, he developed his "sprung rhythm" technique, which attempts to reflect speech rhythms by using a prosody based on the number of stresses (not the feet) in a line, with unaccented syllables being discounted. He combines this distinctive approach to metre with extensive use of alliteration and assonance. His formal innovation was complemented by his ideas on "inscape", the term he coined to describe the distinctive spiritual essence formed by the parts that make up the organic integrity of a thing, and "instress", the energy which secures this coherence and which radiates from the inscape into the mind of its beholder.

"The Wreck of the Deutschland" (written 1876) responds to a shipping disaster, in which five Franciscan nuns were drowned, with a meditation on Christ's passion and an expression of his own faith in God, which links Hopkins's poetic and spiritual beliefs: "His mystery must be instressed, stressed; / For I greet him the days I meet him, and bless when I understand." It was followed by "The Windhover" and "Pied Beauty" (written 1877). His poetry was unknown during his own life-time, but became influential after his friend Robert Bridges's posthumous edition, *Poems* (1918).

Among his other best-known poems are the early "Heaven-Haven" and the late "Carrion Comfort" (one of his "terrible" sonnets) and "That Nature is a Heraclitean Fire", a powerful poetic statement of Christ's immanence in humanity.

Victorian Prose

The rapid social changes caused by the Industrial Revolution and the challenge to traditional beliefs brought about by Darwin's theory of evolution, the Higher Criticism of the Bible and a range of other scientific and intellectual developments led to the emergence of some of English literature's most extraordinary prose writers, whose works combined artistic and cultural concerns with broader social and religious commentary.

Thomas Carlyle (1795–1881)

One of the most influential thinkers of the nineteenth century, Carlyle came from a Scottish Presbyterian background and was strongly influenced by the German philosophical tradition. *Sartor Resartus* (1833–4), an eccentric work, starting from the proposition that clothes represent the provisional nature of the human condition, introduced his mannered prose style, full of neologisms, exclamations and archaisms, which later came to be known as "Carlylese". His fame as a historian was assured with the publication of his *History of the French Revolution* (1837). *On Heroes, Hero-Worship and the Heroic in History* (1841) discusses the characteristics of representative heroes, such as Odin, Muhammad, Dante and Rousseau. *Past and Present* (1843), which looks back to medieval times to comment on the situation of the new urban poor, provided an inspiration for certain sections of the working men's movement. However, although his writing is informed by a strong sense of social conscience, Carlyle's anti-democratic identification with heroic leader figures led to a decline in his reputation in the twentieth century.

John Ruskin (1819–1900)

Ruskin's work brings together a broad range of artistic, philosophical and social concerns. He first achieved fame as an art critic with *Modern Painters* (Vol. I, 1843; later volumes, 1846–60). This was followed by *The Seven Lamps of Architecture* (1849) and *The Stones of Venice* (1851-3), the work that best demonstrates his extraordinary capacity for blending specialist art criticism with commentary on the social implications of cultural production. It broadens out from an attack on the romantic sentimentalization of Venetian architecture to contrast the degradation of industrial society's working practices with the labour conditions that existed in feudal times. His work as an art critic championed the Gothic and the paintings of the Pre-Raphaelite Brotherhood.

He became a major campaigner for social reform and was active in a wide range of causes. Like William Morris, he was an advocate of craftsmanship and an opponent of what he saw as the deleterious human consequences of mass production.

During his later years he started an unfinished autobiography, *Praeterita* (1885 9).

William Morris (1834–96)

The main founder of the Arts and Crafts Movement, Morris pioneered new standards in architecture, interior furnishings, printing, bookbinding, textiles and glasswork. He was associated with the Pre-Raphaelites and like them and like Ruskin, he attempted to counter what he saw as the vulgarity of contemporary taste by returning to medieval practices. Morris's ideas about design were accompanied by strong socialist convictions and he also produced numerous literary works. His poetic sequence, *The Earthly Paradise* (1868–70) is a late Romantic work which draws on Norse and other mythologies. The prose work, *A Dream of John Ball* (1888) looks back to the fourteenth-century Peasants' Revolt to find alternatives to the values of contemporary England; the utopian fantasy, *News from Nowhere* (1890) looks forwards to a socialist future in which craftsmanship has replaced factory production.

The Aesthetic Movement

Another strain in later nineteenth-century thinking came to the fore in the *fin de siècle* aesthetic movement, which rejected the utilitarianism that marked much Victorian intellectual inquiry in favour of a belief in "art for art's sake". This phrase was coined by Walter Pater, in the conclusion to his *Studies in the History of the Renaissance* (1873), but Pater subsequently distanced himself from it.

Pater's best-known work, *Marius the Epicurean* (1885), is a philosophical romance set in ancient Rome, written in his characteristically polished prose. Other prominent figures in the movement included Max Beerbohm, Oscar Wilde and the illustrator Aubrey Beardsley, art editor of the periodical *The Yellow Book* (1894–7), which shocked many of its late Victorian readers with what they saw as its decadence.

Victorian Drama

The nineteenth century was not one of the great ages of the English theatre, but during the Victorian era, plays such as Dion Boucicault's *London Assurance* (1841) and Leopold Lewis's *The Bells* (1871), the story of a man haunted to his death by a murder he has committed, were highly regarded for their melodramatic appeal. Towards the end of the century melodrama became the object of parodies such as Gilbert and Sullivan's *Ruddigore* (1887), while A.W. Pinero's The *Second Mrs Tanqueray* (1893), an attack on the sexual double standards of the day, achieved fame as a more serious treatment of Victorian hypocrisy.

Oscar Wilde (1854–1900)

The hypocrisy of the period is also a prime target of the plays of Oscar Wilde, whose comedy of manners *The Importance of Being Earnest* (1895), in which brilliant epigrams combine with comedy based on mistaken or false identities, is one of the wittiest plays in the English language. Wilde's other comedies, *Lady Windermere's Fan* (1892), *A Woman of No Importance* (1893) and *An Ideal Husband* (1895), are also memorable for their aphorisms and their ingenious manipulation of situation.

Wilde also produced notable work in other genres, including *The Picture of Dorian Gray* (1890), a novel in which the Faustian protagonist sells his soul for eternal youth and which suggests the decadence underlying the genteel facade of polite society, and *Lord Arthur Savile's Crime and Other Stories* (1891). The poem *The Ballad of Reading Gaol* (1898) was a product of his experience serving a two-year sentence in the jail after a conviction for homosexuality.

George Bernard Shaw (1856–1950)

By the end of the nineteenth century, the influence of the Norwegian playwright Henrik Ibsen's naturalistic drama began to be felt in Britain and the early plays of the Irish-born George Bernard Shaw, such as *Arms and the Man* (1894), *The Devil's Disciple* (1897) and *You Never Can Tell* (1899), show the influence of his revolt against the artificiality of nineteenth-century stage conventions.

Shaw was a Fabian socialist, whose dramas of ideas are enlivened by memorable characterization and witty dialogue. His finest plays belong to the first part of the twentieth century. They include *Man and Superman* (1903), *Major Barbara* (1907) and *Pygmalion* (1913), the story of the metamorphosis of a Cockney flower-girl into a lady, from which the musical *My Fair Lady* (1956) was adapted. In *Heartbreak House* (1920), the house of the title suggests the condition of England at the outbreak of World War I and the play's characters are riddled with uncertainties. *Saint Joan* (1923) presents Joan of Arc as a woman born ahead of her time. Shaw's other plays include *Candida* (1897), *Caesar and Cleopatra* (1899), *Captain Brassbound's Conversion* (1900), *The Doctor's Dilemma* (1906), *Back to Methuselah* (1922), *The Apple Cart* (1929) and *The Millionairess* (1936). He was awarded the Nobel Prize for Literature in 1925.

W.B. Yeats (1865–1939) and the Irish Literary Renaissance

One of Ireland's greatest poets, Yeats's early work was inspired by traditional Celtic mythology and the beginnings of what was to be a life-long interest in magic and the occult. He was the leading figure in the Irish literary renaissance of the late nineteenth and early twentieth centuries, a movement which endeavoured to counteract the predominantly negative view of the country's culture that was prevalent in his youth and which can be seen as an artistic equivalent of Irish political nationalism. His anthology *The Celtic Twilight* (1893) gave a name to a pre-existing vogue for Gaelic legend and played a significant role in its dissemination.

Yeats's early verse was primarily lyrical. It includes poems such as "The Lake Isle of Innisfree" and "When You Are Old", along with treatments of mythical subjects such as "Fergus and the Druid" and "Cuchulain's Fight with the Sea". In the late 1890s, along with Lady Augusta Gregory and others, he helped found the Irish Literary Theatre, a group dedicated to establishing a national drama, and his play *The Countess Cathleen* (1899) was its first production. The group's efforts resulted in the founding of Ireland's most famous theatrical venue, the Abbey Theatre, which opened in Dublin in 1904. His other plays include his best-known dramatic work, the one-act *Cathleen Ni Houlihan* (1902), which again took its subject from traditional Irish legend, *Deirdre* (1907), *At the Hawk's Well* (1915) and *Purgatory* (1938).

The Later Period

Yeats's later poems blend the lyricism of his early work with a more mature and reflective approach, in which the sometimes gratuitous obscurity of his use of symbols is replaced by a more sustained system of symbolism, based on the Italian philosopher Giambattista Vico's view of history and explained in his prose work, *A Vision* (1937). Many of his major poems appear in the collections, *The Wild Swans at Coole* (1919), *Michael Robartes and the Dancer* (1921) and *The Tower* (1928). Other volumes include *The Wanderings of Oisin* (1889), *The Rose* (1893), *The Wind Among the Reeds* (1899), *The Green Helmet* (1910), *Responsibilities* (1914), *The Winding Stair* (1933) and *Last Poems* (1939). Yeats's finest poems include "Easter 1916", an elegiac response to the political uprising of that year, the powerfully cryptic "Second Coming", in which artistic and political concerns are fused, and two of the greatest poetic meditations on ageing in the English language: "Sailing to Byzantium" and "Among School Children". Yeats became a member of the Irish Senate in the 1920s and was awarded the Nobel Prize for Literature in 1923.

J.M. Synge (1871–1909) and Later Irish Dramatists

Along with Yeats and Lady Gregory, Synge was the other key figure in the movement that led to the opening of the Abbey Theatre. His contribution to the Irish literary renaissance differs from Yeats's in that it lacks obvious political commitment. His plays were inspired by a series of visits to the remote Aran Islands between 1898 and 1902 and are lyrical homages to the individualism and humour of the peasantry of the West of Ireland. They include the one-act *In the Shadow of the Glen* (1903) and *Riders to the Sea* (1904), his masterpiece *The Playboy of the Western World* (1907), in which he achieved his finest representation of the speech of the region, albeit while incurring the wrath of Irish patriots who objected to his debunking of idealized views of the West, and *Deirdre of the Sorrows* (1910), in which he took his subject from Irish mythology.

Subsequent landmarks in Irish theatre include Sean O'Casey *Juno and the Paycock* (1924), *The Plough and the Stars* (1926) and *The Silver Tassie* (1928), Brendan Behan's *The Quare Fellow* (1954) and *The Hostage* (1958), Brian Friels's *Translations* (1980) and *Dancing at Lughnasa* (1990) and Billy Roche's *Amphibians* (1992).

MODERN FICTION

Henry James (1843–1916)

Along with Joseph Conrad, who was also born in the mid-nineteenth century, James was one of the founding figures of the modern novel in English. The fiction of James and Conrad is modern in its emphasis on the subjectivity of perceptions and the relativism of beliefs and its employment of narrative strategies that reflect this shift in focus. James was also the first great theorist of the modern novel, producing a body of critical work that argued for a movement away from the "loose and baggy monsters" of nineteenth-century fiction towards a more serious "art of fiction" of the kind developed by Flaubert and Turgenev in France. He was a particular pioneer of what he variously called "the point of view", "centres of consciousness" and "scenic reflectors", *i.e.* the angle of vision from which a narrative is seen and told.

His Early Work

James was born in the United States and his early novels *Roderick Hudson* (1875), *The American* (1877) and *The Europeans* (1878) introduce the subject that dominates much of his fiction, the "international theme": the contrast between English and American manners. *Roderick Hudson* and *The American* both describe the experiences of American innocents abroad in Europe, though ultimately their protagonists suffer very different fates. *The Europeans* reverses the formula by taking "European" American expatriates to Massachusetts and dramatizing the differences between their lifestyles and those of their New England cousins.

In the novella, *Daisy Miller* (1878), James's first notable popular success, another American innocent becomes a victim of European experience, when she flouts social conventions and dies after contracting malaria in the symbolic arena of the Coliseum. The masterpiece of the first phase of James's career, *The Portrait of a Lady* (1881), is the subtlest and most fully developed of his early explorations of the ironies surrounding the encounter between American and European culture and its characters, including the heroine Isabel Archer, and situations are among his most finely drawn.

His Later Work

Innocence and experience also lie at the heart of James novels which desert the international theme, such as *What Maisie Knew* (1897), *The Spoils of Poynton* (1897) and *The Awkward Age* (1899), and his classic "ghost story", *The Turn of the Screw* (1898). *The Turn* uses point of view in a highly complex way, leaving its readers unsure as to whether its narrator-protagonist, a governess figure in the tradition of Jane Eyre, is reliable or unreliable and having to choose between various possible explanations of the apparitions she has "seen", including whether she is really looking at ghosts or hallucinating, possibly because of sexual repression.

In the 1890s James aspired to become a successful dramatist, but after the failure of his play *Guy Domville* (1895) on the London stage, he returned to fiction. In the same decade he wrote most of his best-known short stories, publishing the collections *The Lesson of the Master* (1892), *The Real Thing* (1893), *Terminations* (1895) and *Embarrassments* (1896), which includes "The Figure in the Carpet".

Three Late Masterpieces

In his three late masterpieces, *The Wings of the Dove* (1902), *The Ambassadors* (1903) and *The Golden Bowl* (1904), James returned to variations on the international theme. Written in an often-labyrinthine prose style, they become detective-stories of consciousness, in which the characters struggle to come to terms with hidden forces of betrayal *and* their own capacity for self-deception. His other novels include *Washington Square* (1880), *The Bostonians* (1886) and *The Princess Casamassima* (1886). His volumes of critical prose include *French Poets and Novelists* (1878), *The Art of Fiction* (1885) and *Notes on Novelists* (1914).

H.G. Wells (1866–1946)

Wells's writing blends invention with socialist commentary on the present and future state of society and after World War I he mainly produced novels of ideas that took an increasingly pessimistic view of the direction in which civilization was moving. His beliefs about literature represent an opposite extreme from those of Henry James, with whom he engaged in a debate about the nature and function of fiction. Wells took the view that novels should serve a melioristic function and maintained that their form should reflect the disorderliness of experience; James argued for "selection" rather than "saturation" and for the need for art to shape "reality".

Wells's most significant novels appeared in the early years of his career and fall into two groups: science-fiction romances, mainly written in the 1890s, and social comedies, mainly written in the first years of the twentieth century. His science fiction includes *The Time Machine* (1895), *The Island of Dr Moreau* (1896), *The Invisible Man* (1897) and *The War of the Worlds* (1898). Unlike the slightly earlier science-fiction writing of Jules Verne, where the main interest is in science itself, Wells's work in the genre usually offers allegories of contemporary social situations rather than prophecies of the future or adventure-stories. Thus the story of a Martian invasion of London in *The War of the Worlds* hints at the dangers of imperial complacency.

Wells's social comedies are novels in the tradition of Dickens, which characteristically blend comedy and pathos in their accounts of lower middle-class "little men" struggling to achieve a better life, often through self-education. They include *Love and Mr Lewisham* (1900), *Kipps* (1905), *Tono-Bungay* (1909) and *The History of Mr Polly* (1910).

Joseph Conrad (1857–1924)

Although, like Henry James, Conrad is generally regarded as an English novelist, he was born into a Polish family in a part of the Ukraine that had been annexed by Russia. This and his subsequent twenty-year career as a merchant sailor who travelled to all the world's continents gave him first-hand insight into many forms of imperialism, which would become a central subject in his fiction. His first novel *Almayer's Folly* (1895) did not appear until he was thirty-eight, a year after he had completed his final voyage as a sailor. He was subsequently permanently resident in England, but most of his fiction was set in countries he had visited during his years at sea.

Conrad's Complex Structures

Conrad's fiction creates a relativistic atmosphere by employing complex and unchronological time-structures, multiple points of view and narrators whose reliability is open to question. It reveals an ironic scepticism about human motivation, particularly as manifest in the colonizing enterprises of European nations in the late nineteenth-century phase of imperialist expansion. In his most famous work, the novella *Heart of Darkness* (1902), the narrator Marlow journeys upriver in an unnamed Central African country, clearly based on the Congo, in search of Kurtz, an ivory-trader and supposed emissary of European light, whom it appears has become devilishly corrupt and insane. The story provides an indictment of the economic exploitation involved in colonialism, but has itself been attacked as "racist", particularly by African commentators such as the novelist Chinua Achebe, on the grounds that its Africans are shadowy beings, denied any life of their own. Marlow is also the narrator of another of Conrad's finest works, the novel *Lord Jim* (1900), a tale of lost honour mainly set in the Arabian Sea and Sumatra, and of the short story "Youth" (1902) and the novel *Chance* (1913–14), his first popular success.

Conrad's Masterpiece

Conrad's masterpiece *Nostromo* (1904) is a study of the corrosive power of materialism, set in the fictional South American republic of Costaguana. Again the novel moves between several characters and viewpoints to demonstrate its thesis that "There was something inherent in the necessities of successful action which carried with it the moral degradation of the idea". In *The Secret Agent* (1907), Conrad explores similar issues in a story set in Britain. Its detached, ironic account of an anarchist cell's attempt to blow up the Greenwich Observatory suggests the relationship between corruption in personal and public spheres. Conrad's other novels include *An Outcast of the Islands* (1896), *Under Western Eyes* (1911), *Victory* (1915), *The Rescue* (1920) and *The Rover* (1923).

Much of his best work is in the form of shorter fiction. In addition to "Youth" and *Heart of Darkness*, his novellas and stories include "The *Nigger* of the 'Narcissus'" (1897), "Typhoon" (1902), "Amy Foster" (1903), "The Secret Sharer" (1912) and *The Shadow-Line* (1917). *The Mirror of the Sea* (1906) and *A Personal Record* (1912) are volumes of his reminiscences.

Rudyard Kipling (1865–1936)

Born in Bombay (now Mumbai), Kipling enjoyed an unparalleled reputation as the poet of the British Empire and most of his work expresses supposed virtues of the imperialist ethic, such as self-reliance and courage in adversity. *Plain Tales from the Hills* (1888) and *Soldiers Three* (1888) are collections of his early short stories about Anglo-Indian life; his poems of the same period are collected in *Barrack-Room Ballads* (1892) and other volumes. His masterpiece *Kim* (1901) is a novel of espionage, which transcends the "boy's own" adventure mould in which it is cast to provide an encyclopaedic view of aspects of Indian life, especially during its account of the orphan protagonist's picaresque journey along the Great Trunk Road.

His Children's Books

Kipling was also a highly popular author of children's books and his writing in this genre includes *The Jungle Book* (1894), *The Second Jungle Book* (1895), *Just So Stories* (1902) and *Puck of Pook's Hill* (1906). His other works include the novel, *The Light That Failed* (1890), *Stalky and Co.* (1899) and also a posthumously published volume of autobiography, *Something of Myself* (1937). He became the first English winner of the Nobel Prize for Literature in 1907.

His reputation declined after his death, but with the passage of time it has enjoyed a partial rehabilitation, as more measured assessments have seen beyond the stereotypical view of him as a jingoistic imperialist. Although his writing *is* frequently chauvinistic, it demonstrates an insider's sensitivity to aspects of Indian life that was rare among his Anglo-Indian contemporaries.

His most famous poems include "Mandalay," "The White Man's Burden", "Gunga Din", "Recessional" and "If" ("If you can meet with Triumph and Disaster/ And treat those two impostors just the same;/ ... you'll be a Man, my son!").

E.M. Forster (1879–1970)

On the surface the five novels E.M. Forster published during his life-time are social comedies in the tradition of Fielding and Jane Austen. Liberal humanist in outlook, they characteristically compare different sets of social mores, both within and outside England. *Where Angels Fear to Tread* (1905) and *A Room with a View* (1908) contrast the intolerance of certain sectors of English middle-class society with the more open-minded attitudes of Italy. In *The Longest Journey* (1907), the Cambridge-educated hero Rickie's experience of marriage and family life ends in tragedy. Forster's most accomplished "English" novel, *Howards End* (1910), is a late Edwardian Condition of England novel, in which ownership of the rural house of the title becomes the central tearing-point of the plot. In a contrast reminiscent of that between city and country values in Jane Austen's *Mansfield Park*, the stability represented by the house is imperilled by a world of "telegrams and anger" that threatens to overtake the more cultured values initially associated with it.

A Passage to India

Howards End's epigraph, "Only connect", typifies Forster's insistence on the need for cultural dialogue and this theme is central to his finest novel, *A Passage to India* (1924), in which symbolic patterns that sometimes suggest mystical connections belie the view that he was simply a writer of social comedies. The novel grew out of his experience in India as secretary and companion to a maharajah, which he wrote about in *The Hill of Devi* (1953). It deals with three aspects of Indian life: the côterie society of an Anglo-Indian Club, whose exclusivity Forster satirizes; the abortive attempt by a liberal Englishman and a Muslim doctor to develop and sustain a friendship; and a more spiritual "Hindu" India, which offers a possibility for "connections" across cultures, where the other areas of contact have failed.

Maurice

After Forster's death, a sixth novel, *Maurice* (1971), written around 1914 but previously suppressed because of its overtly homosexual theme, was published. It partly reshaped views of Forster's earlier fiction, in which marriage and heterosexual love are treated in a manner that is at best conventional and at worst uncomfortable, by suggesting an alternative way of viewing the male friendships in these novels.

Forster also wrote numerous short stories, collected in *The Life to Come* (1972), and an influential study of the novel, *Aspects of the Novel* (1927), notable for its emphasis on "rhythm", the use of recurrent images as a structuring device for fiction and for the distinctions he drew between "flat" and "round" characters and between "story" and plot". As an example of the latter distinction, he maintained that "The king died and then the queen died" is a story, while "The king died, and then the queen died of grief" is a plot. His numerous essays are collected in *Abinger Harvest* (1936) and *Two Cheers for Democracy* (1951).

James Joyce (1882–1941)

Joyce was born into an Irish Catholic family, but like Stephen Dedalus, the protagonist of his first novel, *A Portrait of the Artist as a Young Man* (1916), he became increasingly disillusioned with the shaping forces of his upbringing, Catholicism, Irish nationalism and family allegiances, and replaced early thoughts of entering the priesthood with a quasi-religious devotion to art. He left Dublin in 1904 and lived in mainland Europe for the remainder of his life. However, all his work is about Dublin and he once said, "if I can get to the heart of Dublin, I can get to the heart of all the cities in the world".

Early Writings

Written in a sparse and unembellished prose style, *Dubliners* (1914) is a collection of short stories about aspects of the city's life. Joyce's declared aim was "to write a chapter of the moral history of my country" and the volume offers an indictment of what he saw as the "paralysis" stifling individual growth in Ireland. The stories generally end with an "epiphany", a sudden moment of revelation, in which characters achieve an awareness hitherto lacking to them.

The main emphasis of *A Portrait of the Artist as a Young Man* is on the growth of the artist, Stephen Dedalus's consciousness. The novel describes his struggle against the forces that threaten to hinder his development and his rejection of the priesthood and is notable for its use of the stream-of-consciousness technique. Beginning with a form of monologue that attempts to convey the thought-processes of a young child, it moves through a range of increasingly complex styles and culminates with Stephen's commitment to an art based on "silence, exile and cunning". By the conclusion, the novel has become an artistic manifesto that prepares the way for the task Joyce was to undertake in his masterpiece, the comic epic *Ulysses* (1922).

His Masterpiece

In the first three sections of *Ulysses*, Stephen Dedalus is once again central and the emphasis is on the problems facing the Joycean artist figure. Subsequently, the main protagonist is the Irish-Jewish advertisement canvasser, Leopold Bloom, an "ordinary man" who is Joyce's modern-day Ulyssses. Bloom provides a focus for representing a broader cross-section of Dublin life and the main part of the novel gives an account of his wanderings through the streets of the city on a single day in 1904, Joyce's equivalent of Homer's narrative of Ulyssses' ten-years of travelling in the Eastern Mediterranean.

Ulysses is divided into eighteen sections, each of which is written in a different style, chosen for its relevance to the material it portrays. Joyce also takes the stream-of-consciousness technique further, employing variations suited to the thought-processes of the particular character being portrayed. It concludes with a monologue by its third major character, Bloom's wife, Molly, one of the most fully realized characters in Modernist fiction. Written in an unpunctuated prose that endeavours to mirror the flow of her emotions, Molly's monologue is Joyce's most brilliant *tour de force* in the use of the stream-of-consciousness technique.

Joyce's final novel, *Finnegans Wake* (1939), was his most ambitious. It describes the dreams of H.C. Earwicker, his wife Anna Livia Plurabelle and their children, during the course of a single Dublin night. From this limited vantage point, Joyce expands outwards to encompass an encyclopaedic range of human experience. The novel's dream-like method is indebted to contemporary psychoanalytic theory. It is written in a style full of portmanteau words and neologisms, presenting its readers with a level of difficulty besides which *Ulysses* seems comparatively straightforward.

Virginia Woolf (1882–1941)

Along with Joyce, his exact contemporary, Virginia Woolf pioneered the use of the stream-of-consciousness monologue as a technique for representing the flow of subjective mental processes, which is central to the view of character embodied in her novels. In her essay "Modern Fiction" (1925), she wrote, "Examine for a moment an ordinary mind on an ordinary day. The mind receives a myriad impressions—trivial, fantastic, evanescent, or engraved with the sharpness of steel. From all sides they come, an incessant shower of innumerable atoms; and as they fall ... the accent falls differently from of old."

The technique can be seen at its best in her three finest novels, *Mrs Dalloway* (1925), *To the Lighthouse* (1927) and *The Waves* (1931). As with Joyce's *Ulysses*, the action of *Mrs Dalloway* takes place on a single day, but the focus on the protagonist's consciousness sketches in her previous life through her memories, as well as providing access to her innermost feelings. The intensely subjective action of *To the Lighthouse* takes place on two days ten years apart. These are separated by a short central section, in which catastrophic external events that have taken place in the intervening years are recorded in a shockingly perfunctory way. The novel's characters live in solipsistic mental worlds and loneliness and the difficulty of communication are among its major themes, as is a quest for stability amid the flux of experience.

The most experimental of Woolf's novels, *The Waves* follows the lives of six characters from infancy to old age through their own interior monologues, which are punctuated by passages that describe natural phenomena and seasonal changes.

Her most extravagant novel, *Orlando* (1928), is a mock-biography of its androgynous protagonist, which ranges across four centuries. Her other novels include *Night and Day* (1919), *Jacob's Room* (1922) and *The Years* (1937).

Woolf and First-Wave Feminism

Woolf's fiction interrogates the gender norms of her day and her non-fiction writing, such as *A Room of One's Own* (1929), in which she specifically discusses the problems facing the female artist, made an important contribution to the first wave of twentieth-century feminism. Its lesser-known sequel, *Three Guineas* (1938), analyses the social and economic exclusion of women, particularly in higher education, and suggests that they could provide a challenge to authoritarianism and the rise of fascism. Her collections of essays include *The Common Reader* (1925), *The Second Common Reader* (1933) and *The Death of the Moth* (1942). Her final novel *Between the Acts* (1941) was published posthumously, after she had committed suicide by drowning herself.

Woolf was a leading figure in the Bloomsbury Group, a circle of writers and artists committed to moving culture beyond what they saw as the narrowness of Victorian artistic and moral standards. Other members included the artist Roger Fry, the economist John Maynard Keynes, the biographer Lytton Strachey and the writers E.M. Forster, Vita Sackville-West and Woolf's husband, Leonard, founder of the innovative Hogarth Press and author of the novel *The Village in the Jungle* (1913).

D.H. Lawrence (1885–1930)

Lawrence shared the Modernist interest in inner mental states, rejecting what he referred to as "the old stable ego of the character" for a view of consciousness founded on the ebb and flow of emotions. Though his fiction is less abstract than that of his Modernist contemporaries, Joyce and Woolf, he also challenged the conventions of earlier fiction. He saw the novel as a genre that "can inform and lead into new places the flow of our sympathetic consciousness" and developed a theory of organic form, in which novels create their own spontaneously developed shape, to embody this.

Sons and Lovers

His semi-autobiographical novel, *Sons and Lovers* (1913), set in the Nottinghamshire mining area where he grew up, is Lawrence's *Portrait of the Artist as a Young Man*, though his artistic technique is very different from Joyce's. It describes the early life and loves of its hero, Paul Morel, particularly his Oedipal feelings for his mother and his relationships with two contrasted women, the puritanical Miriam and the more sensuous Clara. It was followed by two of Lawrence's finest novels, *The Rainbow* (1915) and *Women in Love* (1920). *The Rainbow* deals with the quest of three generations of the Brangwen family to achieve the harmony between flesh and spirit suggested by the image of the rainbow itself. It represents Lawrence's first major development of his ideas on sexual "otherness". *Women in Love* was originally conceived as a sequel to *The Rainbow*, but in its finished form is markedly different in focus and approach, though the two novels share a common character, Ursula Brangwen.

In *Women in Love* Lawrence sets the relationships of a central quartet of characters against the backcloth of an England in transition, which he views more pessimistically than in *The Rainbow*.

Lawrence left England in 1919 and subsequently lived in Italy, Ceylon, Australia, Mexico and New Mexico, writing novels set in three of these countries: *Aaron's Rod* (1922) in Italy, *Kangaroo* (1923) in Australia and *The Plumed Serpent* (1926) in Mexico. At their worst, these more hastily composed novels—*Kangaroo* is said to have been written in six weeks—are verbose and art is replaced by overwritten polemic. They share a common concern with "leadership", turning towards "dark gods" and an anti-democratic view of society.

Lady Chatterley's Lover

The sexually explicit accounts of lovemaking and the use of four-letter words in Lawrence's final and most controversial novel, *Lady Chatterley's Lover* (1928), led to its full text being banned in Britain and the United States for thirty years. Then, in 1960, a landmark court case, which had an important effect on English censorship laws, found in favour of an unexpurgated Penguin edition. The novel's graphic account of the titular heroine's turning away from her impotent husband for a passionate relationship with the gamekeeper on his estate marked a return to Lawrence's best work. *The First Lady Chatterley* (1944) and *John Thomas and Lady Jane* (1972) are earlier versions.

His Shorter Fiction

Lawrence's shorter fiction contains some of his finest writing. His short story collections include *The Prussian Officer* (1914), *England, My England* (1922), *The Woman Who Rode Away* (1928) and *Love among the Haystacks* (1930); his novellas include *The Fox* (1922), *The Ladybird* and *The Captain's Doll* (1923), *St Mawr* and *The Princess* (1925) and *The Virgin and the Gipsy* (1930). His travel-writing includes three books about Italy, *Twilight in Italy* (1916), *Sea and Sardinia* (1921) and *Etruscan Places* (1932), and *Mornings in Mexico* (1927). He also published the novels, *The White Peacock* (1911), *The Trespasser* (1912), *The Lost Girl* (1920) and (with M.L. Skinner) *The Boy in the Bush* (1924).

The Novel in the 1930s and 1940s: Huxley and Orwell

Influenced by the Depression, the rise of Fascism and events such as the Spanish Civil War, novelists of the 1930s turned away from the artistic experimentalism and interest in inner mental states that had characterized the fiction of their Modernist predecessors towards more realistic modes of writing and a more direct engagement with social issues.

Aldous Huxley's novel, *Brave New World* (1932) typifies the period's sense of the threat posed by totalitarianism. George Orwell's *Keep the Aspidistra Flying* (1936) and *Coming Up for Air* (1939) reflect his concern with an England in transition. Huxley's other novels include *Antic Hay* (1923), *Point Counter Point* (1928) and *Eyeless in Gaza* (1936); Orwell also wrote *Burmese Days* (1934) and *A Clergyman's Daughter* (1935).

Subsequently Orwell's critique of society turned to more pessimistic allegorical modes: *Animal Farm* (1945) uses the form of the animal fable for a satirical attack on Stalinist Communism ("All animals are equal, but some animals are more equal than others"), while *Nineteen Eighty-Four* (1949) is a science-fiction novel in the tradition of *Brave New World*, in which a future dystopia offers a thinly-veiled picture of the present.

Christopher Isherwood and Evelyn Waugh

Christopher Isherwood's novels set in the Berlin of the early 1930s, *Mr Norris Changes Trains* (1935) and *Goodbye to Berlin* (1939), a sequence of six diaries and sketches, are witty portraits of "lost" people living in a society moving towards fascism. The opening diary in the latter work contains the famous passage in which Isherwood outlines his quasi-objective narrative method: "I am a camera with its shutter open, quite passive, recording, not thinking". This provided the title for John van Druten's 1951 stage dramatization, which took Isherwood's most memorable character, the cabaret performer Sally Bowles, as its central figure and which provided the basis for the musical *Cabaret* (1966), a work that also drew on Bertolt Brecht and Kurt Weill's *Threepenny Opera* (1928).

Evelyn Waugh's witty portraits of the upper echelons of English society in his novels of the 1930s—*Vile Bodies* (1930), *Black Mischief* (1932), *A Handful of Dust* (1934) and *Scoop* (1938)—established him as the finest satirist of his generation. In his later work, which includes his most popular novel, *Brideshead Revisited* (1945) and his World War II "Sword of Honour" trilogy, *Men at Arms* (1952), *Officers and Gentlemen* (1955) and *Unconditional Surrender* (1961), his characteristic wit is combined with a more elegiac perspective.

Other novelists at the height of their powers during the lean publishing years of the 1940s include Joyce Cary, L.P. Hartley, Elizabeth Bowen, Henry Green and Elizabeth Taylor.

Graham Greene (1904–91)

Beginning with *The Man Within* (1929), Greene's career spanned six decades. In his early "trilogy", *Brighton Rock* (1938), *The Power and the Glory* (1940) and *The Heart of the Matter* (1948), characters wrestle with dilemmas posed by Catholic consciences in varied settings: an English seaside resort, Mexico and West Africa respectively. Many Greene novels achieve their effect through placing their characters in unromantic expatriate situations, including Vietnam in *The Quiet American* (1955), a Congo leper colony in *A Burnt-Out Case* (1961), which takes an Albert Schweitzer-like figure for its protagonist, and Argentina in *The Honorary Consul* (1973). In these novels set in "faraway" places, the plot frequently turns upon an incident in which the central character grapples with a difficult moral choice. *The End of the Affair* (1951) employs a similar pattern for a novel in which the action takes place in London during and just after World War II.

The "Entertainments"

Greene made a distinction between his novels and his "entertainments", several of which were developed as film-scripts. The "entertainments", which draw on the conventions of the thriller, include *Stamboul Train* (1932), *The Confidential Agent* (1939), *The Third Man* (1950), a work set in post-war Vienna and adapted from Greene's screenplay for Carol Reed's highly acclaimed 1949 film, *Loser Takes All* (1955) and *Our Man in Havana* (1958). His numerous other novels include *It's a Battlefield* (1934), *England Made Me* (1935), *The Comedians* (1966), *Travels with My Aunt* (1969), *The Human Factor* (1978) and *Doctor Fischer of Geneva* (1980).

Greene also wrote a number of plays, the travel books *Journey without Maps* (1936) and *The Lawless Roads* (1939) and the autobiographical volumes *A Sort of Life* (1972) and *Ways of Escape* (1980).

Samuel Beckett (1906–89)

Beckett is best known for his absurdist play, *Waiting for Godot* (*En attendant Godot* 1952; English translation 1953), a work devoid of conventional action in which two tramps spend their time in seemingly idle chatter, while they wait for the eponymous Godot, who never arrives. He was also a major novelist in the tradition of his Irish compatriot, James Joyce, whom he followed into exile in Paris. He wrote the majority of his plays and novels in French, subsequently translating them into English.

The protagonists of his finest achievement in fiction, the trilogy of novels, *Molloy* (1951), *Malone Dies* (1951) and *The Unnamable* (1953), probe the limits of language in a struggle to understand their selfhood. The minimalist action of the three novels is pared down to a point where it is virtually non-existent and fiction's ability to encapsulate external reality is called into question. Beckett also wrote the novels *Murphy* (1938) and *Watt* (1953) and the short story collection *More Pricks than Kicks* (1934). His other plays include *Endgame* (1957), *Krapp's Last Tape* (1958), *Happy Days* (1961) and *Play* (1964). He was awarded the Nobel Prize for Literature in 1969.

Flann O'Brien's whimsical masterpiece *At Swim-Two-Birds* (1939) is a comic novel in the tradition of Joyce and Beckett. It combines realistic scenes from student life with fantasy and folklore in a highly inventive and self-reflexive fictional farrago. O'Brien's other novels were *The Dalkey Archive* (1964) and *The Third Policeman* (1967).

Novelists of the 1950s and 1960s

The changing face of English society in the post-World War II period had a major impact on the novel in the 1950s and early 1960s, when a number of important works dealing with regional, particularly northern, working-class culture appeared. Prior to this, comic novels such as John Wain's *Hurry On Down* (1953) and Sir Kingsley Amis's *Lucky Jim* (1954) had expressed a new generation's cynicism about the pretensions of their elders, albeit from a more privileged social standpoint.

George Orwell's account of his encounter with northern working-class society in *The Road to Wigan Pier* (1937) was a work which, despite its socialist inclinations, had something of the travel-writer's perspective about it, in that it was written from the viewpoint of a visitor to a "depressed" area hitherto unknown to him. In contrast, the post-war generation of working-class novelists wrote from inside the experiences they depicted.

Screen Adaptations

Several of their most important works were adapted for the screen and became major British films in the 1960s. These include John Braine's *Room at the Top* (1957; film 1959), Alan Sillitoe's *Saturday Night and Sunday Morning* (1958; film 1960), Stan Barstow's *A Kind of Loving* (1960; film 1962) and David Storey's *This Sporting Life* (1962; film 1963). The Londoner B.S. Johnson's work, which is currently enjoying a revival, is working-class fiction of a rather different kind. It combines socialist commitment with formal experimentation and metafictive self-consciousness in a manner rare among his contemporaries. In his box-novel *The Unfortunates* (1969), Johnson invites his readers to shuffle the loose-leaf sections before reading. In *Christie Malry's Own Double-Entry* (1973), he playfully parodies classic techniques of English realism.

Other Novelists of the Period

The most ambitious fictional sequence of the period, Lawrence Durrell's *The Alexandria Quartet* (1957–60), a work made up of a triptych of novels that view the same events from different perspectives and a fourth which is a genuine sequel narrating later occurrences, offers a conscious "challenge to the serial form of the conventional novel". Other novelists who produced important work during this period include Muriel Spark, Angus Wilson, Anthony Powell, whose wide-ranging sequence, *A Dance to the Music of Time*, appeared between 1951 and 1975, and Doris Lessing, whose multi-stranded metafictive novel about "free women", *The Golden Notebook* (1962), is an early classic of the second wave of twentieth-century feminism. Doris Lessing was awarded the Nobel Prize for Literature in 2007. She died in 2013.

Margaret Drabble began her career with *A Summer Birdcage* (1963), *The Garrick Year* (1964) and *Jerusalem the Golden* (1967). Anthony Burgess's virtuoso talent ranged over a broad range of subjects, including a trilogy of novels about Malaya (1956-9), futuristic "ultraviolence" in the verbally innovative *A Clockwork Orange* (1962), which achieved cult notoriety after the banning of Stanley Kubrick's 1971 film version, and Shakespeare's life in *Nothing Like the Sun* (1964). Jean Rhys, whose early work about the lives of single women in Paris and London appeared in the inter-war years, published her masterpiece *Wide Sargasso Sea*, the story of the "mad" first wife of Mr Rochester in *Jane Eyre* in 1966.

Sir William Golding (1911–93)

Golding's first novel *Lord of the Flies* (1954) is a pessimistic twentieth-century reworking of R.M. Ballantyne's *The Coral Island*, in which a group of boys marooned on a desert island gradually revert to savagery. Like all Golding's novels, it is a moral allegory, which probes below the surface of existence to disclose elemental forces in human nature, which are often evil. *Pincher Martin* (1956) is an even bleaker parable of the predicament of a spiritual castaway, while *The Spire* (1964) is a symbolic fable about the building of Salisbury Cathedral. *Rites of Passage* (1980), which won the Booker Prize, is the first part of a maritime trilogy that concludes with *Close Quarters* (1987) and *Fire Down Below* (1989).

His other novels include *The Inheritors* (1955), *Free Fall* (1959), *The Pyramid* (1967), *The Scorpion God* (1971) and *Darkness Visible* (1979). Golding was awarded the Nobel Prize for Literature in 1983 and knighted in 1988.

Dame Iris Murdoch (1919–99)

Murdoch was a professional philosopher, who produced significant work on existentialism and other philosophical systems concerned with free will and ethics. This is reflected in the central conflicts of her novels, which frequently suggest the limits of human freedom. Set in a remote Celtic landscape, suggestive of the west of Ireland, *The Unicorn* (1963) explores issues of altruism and supposed self-sacrifice, reversing conventional notions of guilt and innocence. *A Severed Head* (1961) is a comedy of sexual manners, in which the multiple and often-unexpected comings together among the limited cast of characters border on farce, but also involve a searching investigation of the ethics of personal relationships.

Other Murdoch novels that have received particular praise include *The Bell* (1958), a novel set in a religious community, and the Booker Prize-winning *The Sea, The Sea* (1978). She was a prolific writer, who had a particular talent for observing both "sacred" and "profane" love with an ironist's eye. Her other novels include *Under the Net* (1954), *An Unofficial Rose* (1962), *The Italian Girl* (1964), *The Nice and the Good* (1968), *Bruno's Dream* (1969), *An Accidental Man* (1971) and *The Black Prince* (1973).

John Fowles (1926–2005)

Fowles's reputation mainly rests on *The Magus* (1966; revised version 1977), a powerful and ultimately open-ended *Bildungsroman*, in which reality and illusion are blurred, as the young protagonist is subjected to a seemingly endless series of initiations on a Greek island, and *The French Lieutenant's Woman* (1969), which blends a nineteenth-century story, partly written as a pastiche of a Victorian novel, with self-reflexive commentary on its own processes and the values of the Victorian age. *Daniel Martin* (1977) is a more realistic Condition of England novel, which particularly concerns itself with liberal humanist values. Fowles's other fiction includes the novels *The Collector* (1963), *Mantissa* (1983) and *A Maggot* (1985) and the short-story collection, *The Ebony Tower* (1974). *The Aristos* (1964) is a study in existentialist ethics, which as in Iris Murdoch's novels, are an important area of debate in Fowles's fiction, though he is more positive in his assessment of the individual's capacity for choice.

Sir V.S. Naipaul (1932–)

Born in Trinidad, Naipaul came to Britain in 1950 and has lived in the UK ever since, albeit while travelling extensively to research his often acerbic travel-books about "third-world" societies. These include *The Middle Passage* (1962), *An Area of Darkness* (1964) and *Among the Believers* (1981). His best novels include *A House for Mr Biswas* (1961), a tragic-comic novel of epic sweep about its Trinidadian protagonist's attempt to acquire his own house and with it a sense of self-worth, *The Mimic Men* (1967), *A Bend in the River* (1979) and *The Enigma of Arrival* (1987), a novel that blends thinly-veiled autobiography and reflections on the making of the Wiltshire landscape where the protagonist is now living. Beginning with *In a Free State* (1971), which won the Booker Prize, his work has increasingly broken down the distinction between fiction and non-fiction. Naipaul was knighted in 1990, became the first winner of the David Cohen Prize for "lifetime achievement by a living British writer" in 1993 and was awarded the Nobel Prize for Literature in 2001.

Others novelists of the post-World War II generation of Caribbean migrants to Britain included George Lamming, author of *In the Castle of My Skin* (1953), *Water with Berries* (1971) and *Natives of My Person* (1972), and Sam Selvon, whose memorable novels of Caribbean immigrants' lives in London include *The Lonely Londoners* (1956), *The Housing Lark* (1965) and *Moses Ascending* (1975). The British writer, Colin MacInnes chronicles similar experiences in *City of Spades* (1957).

Angela Carter (1940-92)

Carter's fiction, which combines a materialist critique of society with extravagant fantasies, has often been described as magic realist. It draws on a range of non-realist narrative forms, including fairy tale, science fiction allegory, Hollywood wish-fulfilment fantasy, circus performance and the Gothic. Through these Carter expresses a feminist desire to elude definition by the norms of patriarchal rationalism, providing a variety of alternative representations of gender and sexuality. Her concern with female desire is to the fore in her early novels, *The Magic Toyshop* (1967), *Heroes and Villains* (1969) and *The Infernal Desire Machines of Dr Hoffman* (1972). The short stories of *The Bloody Chamber* (1979) rework fairy tales by Charles Perrault—such as Bluebeard, Beauty and the Beast and Red Riding Hood—as fables of the unconscious that are frequently concerned with sexuality.

Her other major novels are *The Passion of New Eve* (1977), *Nights at the Circus* (1984) and *Wise Children* (1991). Her most significant non-fiction work is the cultural history *The Sadeian Woman* (1979).

Two Campus Novelists

Sir Malcolm Bradbury and David Lodge both combined successful careers as academics and novelists, developing the genre of the campus novel that had been pioneered in England by Amis's *Lucky Jim*. Bradbury's *The History Man* (1975) satirizes the fashionable, but self-serving side of 1960's culture through the figure of a university lecturer in the newly emergent discipline of sociology. His other academic satires include *Eating People is Wrong* (1959), *Stepping Westward* (1965), *Rates of Exchange* (1982) and *Dr Criminale* (1992).

Lodge's *Changing Places* (1975) and its sequel *Small World* (1984) are more formally innovative satires of academic life. His other novels include *The British Museum is Falling Down* (1965), *Nice Work* (1988), a cleverly plotted latter-day Condition of England novel, based around the relationship between the managing director of an engineering firm and a lecturer in English literature, and *Paradise News* (1992).

Two Writers of Fantasy

J.R.R. Tolkien was an academic who made a very different contribution to twentieth-century fiction. His professional expertise in Anglo-Saxon culture informs the mythological landscape of Middle Earth he created for his *Lord of the Rings* trilogy (1954-55). This followed his earlier work *The Hobbit* (1937), in which he introduced the popular characters of the gnome Bilbo Baggins and the wizard Gandalf. Like Mervyn Peake's Gothic *Gormenghast* trilogy—*Titus Groan* (1946), *Gormenghast* (1950) and *Titus Alone* (1959)—*The Lord of the Rings* invents a self-contained fantastic world. Its popularity with readers has increased since Tolkien's death in 1973, making the trilogy a *contemporary* classic.

TWENTIETH-CENTURY POETRY

Poets of World War I

The poetry of the "Great War" gave a new sharpness of perspective to early twentieth-century English verse, which in the preceding years had generally been traditional in both form and theme, as it were celebrating the stability of a seemingly changeless England that was in fact about to disappear forever. Rupert Brooke's question (in his poem "The Old Vicarage, Grantchester"), "And is there honey still for tea?", expresses a mood of Edwardian and Georgian nostalgia that was to be shattered by the advent of the war. Brooke died early in the war, in 1915, and his best-known poem, "The Soldier" ("If I should die think only this of me ..."), conveys an idealistic view of warfare, from which poets who experienced its traumas would soon depart.

Siegfried Sassoon debunked the romantic attitude to war in poems such as "Counter-Attack", "Does It Matter?" and "Suicide in the Trenches". "Dulce et Decorum Est" by Wilfred Owen, who was killed in November 1918, a week before the Armistice was signed, is only marginally less savage in its ironic indictment of the patriotic ethic that sanctioned the atrocities of the war. Several of Owen's major poems, such as "Anthem for Doomed Youth" and "Strange Meeting", conjure up a nightmarish world, which both reflects the horror of the war and expresses a sense of a more general existential futility. Other important poets of World War I include Isaac Rosenberg and Edward Thomas. World War I poetry by women includes work by Rose Macauley and Edith Sitwell.

T.S. Eliot (1888–1965)

Often regarded as the finest and most influential poet of the early twentieth century, Eliot was also a dramatist and a major critic. He studied philosophy at Harvard, where he first developed his ideas on poetry and the literary tradition. Rejecting the Romantic view of the power of the individual imagination, he favoured a classical model of literary influence and drew on a wide range of sources, including the French symbolist poets, the metaphysicals, Dante and Eastern verse and philosophy. The symbolists were an important influence on *Prufrock and Other Poems* (1917), a volume that takes its title from his *vers libre* study of a little man figure, grappling with the realities of daily routine and ageing.

A Growing Reputation

Eliot settled in England in 1915, where, encouraged by his similarly minded compatriot, Ezra Pound, his poetic talent blossomed. *Poems* (1919), which included "Gerontion", a vivid exploration of the psychology of old age, was followed by his masterpiece, *The Wasteland* (1922), a compressed epic dedicated to Pound, who played a crucial role in editing the poem, cutting it down to half its original length. One of the most influential poems of the twentieth century, it draws on a range of literatures and mythologies, particularly the Grail quest, to suggest the aridity of post-World War I urban life and posits the message of the *Bhagavad Gita* as an alternative to Western materialism. The poem's ellipses, sharp juxtapositions and dense allusiveness were highly innovatory when it appeared.

At the same time as Eliot's reputation as a poet was being secured, his essay-collections, *The Sacred Wood* (1920), *Homage to John Dryden* (1924) and *For Lancelot Andrewes: Essays on Style and Order* (1928), established his reputation as a critic. In these he developed his beliefs on the importance of impersonality in art, stressing the need to find an "objective correlative" for the evocation of emotion and, in the highly influential "Tradition and the Individual Talent", arguing that "the most individual parts of [a poet's] work may be those in which the dead poets, his ancestors, assert their immortality most vigorously". In the 1930s Eliot's criticism increasingly turned its attention to broad social issues, deserting the strictly literary for cultural commentary in the tradition of Matthew Arnold.

His later collections include *The Use of Poetry and the Use of Criticism* (1933), *After Strange Gods* (1934), *Notes Towards a Definition of Culture* (1948), *Poetry and Poets* (1957) and *To Criticize the Critic* (1965).

Beginning with *Poems 1909–25* (1925), which includes "The Hollow Men", his poetry became increasingly religious in orientation and in 1927 he became an Anglo-Catholic. His religious ideas were developed in "The Journey of the Magi" (1927) and "Ash Wednesday" (1930) and the major achievement of his later career *Four Quartets* (1943), which brought together "Burnt Norton" (1935), "East Coker" (1940), "The Dry Salvages" (1941) and "Little Gidding" (1942). His children's collection, *Old Possum's Book of Practical Cats* (1939), provided the inspiration for the Andrew Lloyd Webber musical *Cats* (1981).

In the 1930s, Eliot began to write verse drama in an attempt to revive this neglected genre. His most famous play was *Murder in the Cathedral* (1935), a poetic account of the death of Thomas Beckett.

His other plays include *The Family Reunion* (1939), *The Cocktail Party* (1950) and *The Elder Statesman* (1959). Along with the verse drama of Christopher Fry, author of *A Phoenix Too Frequent* (1946) and *The Lady's Not for Burning* (1948), his plays made a significant contribution to English theatre during a fairly barren period.

In 1948, Eliot was awarded both the Nobel Prize for Literature and the Order of Merit. His writing apart, he exercised considerable influence on the course of English poetry as a director of the publishers Faber and Faber, though what was perceived as the conservative tendency of his thinking led some of his younger contemporaries to resist the potent influence of poems such as *The Wasteland*.

Ezra Pound (1885–1972)

Like Eliot, Pound was an American expatriate, who settled in Europe, where in the years immediately before World War I he became a leading figure among the Imagists, a movement which advocated experimentation with verse forms, freedom of expression and the use of concise, concrete imagery. He also played an important role in furthering the careers of a number of major Modernist writers, including those of Joyce and Eliot.

Estimates of his own poetry, which can be recondite and obscure, vary. It includes *Personae* (1910), *Homage to Sextus Propertius* (1919) and his most accessible work, *Hugh Selwyn Mauberley* (1920). In 1925, he published the first volume of his *Cantos*, a project on which he would continue to work throughout the remainder of his career. The *Cantos* form a sequence of epic scope, which, like Eliot's work, draws on an eclectic mélange of cultural traditions in an attempt to evolve an aesthetic practice suitable for the modern age. Pound was also a notable translator, producing free, creative translations from the many literatures and cultures that inform the *Cantos*. These include Anglo-Saxon, Chinese, classical Greek, medieval Provençal and Japanese Noh theatre.

He became disillusioned with what he saw as the decadence of post-World War I Europe and, in the 1930s, his artistic elitism drew him towards Italian fascism. During World War II he broadcast propaganda for the Axis. At the end of the war he was indicted for treason and confined to an American hospital after being declared mentally unfit to answer the charges brought against him. On his release in 1958, he returned to Italy, where he lived for the remainder of his life.

W.H. Auden (1907–73) and the Poets of the 1930s

Auden was the leading figure among a group of writers who attended Oxford in the late 1920s and one of the finest English poets of the twentieth century. His verse is remarkably varied in its subjects, but his early collections, *Poems* (1930), *The Orators* (1932) and *Look Stranger!* (1936), display a recurrent concern with left-wing political causes such as the republican struggle in Spain, which was shared by many of his contemporaries, and post-Freudian psychology. He analyses social issues and sexual repression with a quasi-clinical detachment, using everyday language in an innovative manner, while making encoded references to homosexuality.

Auden moved to the USA in 1939 and deserted the socialist commitment of his 1930's poetry for a more elusive and abstract verse, which partly reflects his return to the Christian beliefs of his early upbringing, but more generally displays a reluctance to being categorized. Subsequent collections include *New Year Letter* (1941; US title *The Double Man*), *For the Time Being: A Christmas Oratorio* (1944), *The Age of Anxiety* (1947), *Nones* (1951), *The Shield of Achilles* (1955), *Homage to Clio* (1960), *About the House* (1965) and *Epistle to a Godson* (1972). With his companion Chester Kallman, he wrote the libretto for Stravinsky's *The Rake's Progress* (1951). Earlier he had collaborated with Christopher Isherwood on the plays, *The Dog beneath the Skin* (1935), *The Ascent of F6* (1936) and *On the Frontier* (1938).

Several of Auden's Oxford contemporaries, including Stephen Spender, C. Day-Lewis, Louis MacNeice, Rex Warner and John Betjeman, went on to become leading poets of their generation. The most important British poet to emerge during the 1940s was the Welsh writer, Dylan Thomas, whose "play for voices" *Under Milk Wood* (1954) was completed shortly before his early death in 1953.

Stevie Smith (1902–71)

Smith's verse is remarkable for its capacity to make poetry out of the everyday, giving voice to the concerns of suburban women and ordinary people more generally with a distinctive and idiosyncratic voice. Her best-known poem, the title-piece of her collection *Not Waving, But Drowning* (1957), in which a dying man says "I was much too far out all my life/ And not waving but drowning", typifies her ability to evoke existential concerns in a casual, seemingly off-hand manner. Smith published her first collection of verse, *A Good Time was Had by All* in 1937 and was also the author of a number of novels, but her reputation grew considerably during her later years, when her public readings of her work, for which she adopted a seemingly naïve girlish persona, attracted a cult following.

Philip Larkin (1922–85) and The Movement

The Movement was the name given to a group of British poets that emerged in the 1950s about the same time as the Angry Young Men of the English stage. They brought a freshness of diction to English poetry, expressing everyday concerns in plain language and traditional verse forms. However, as with the Angry Young Men, their break with earlier literary language was often accompanied by a conservative response to British society. The Movement's poets included Philip Larkin, who was both the finest and the most representative poet of the group, Kingsley Amis, Donald Davie and Thom Gunn. Other notable poets of their generation include R.S. Thomas and D.J. Enright.

Larkin's collections include *The Whitsun Weddings* (1964), and *High Windows* (1974); and the title-poem of the former, "This Be the Verse" and "Church Windows" are among his best-known individual poems. The cool restraint of his verse has been associated with the bleak social climate of post-war England, but it is also expressive of a reticent temperament that was averse to ostentatious displays of emotion.

Ted Hughes (1930–98)

Hughes's work, which introduced a new vitality and urgency into English poetry, has been seen as a reaction against the Movement's devotion to the commonplace. Following in the tradition of D.H. Lawrence's nature poetry, it often uses animals, such as the trickster figure Crow, as anthropomorphic expressions of elemental human instincts operating outside customary social constraints. The poetic intensity of Hughes's verse evokes the raw power of nature and primeval landscapes wounded by the scars of industrialization. His collections include *The Hawk in the Rain* (1957), *Lupercal* (1960), *Wodwo* (1967), *Crow* (1970), *Remains of Elmet* (1979), *Moortown* (1979) and *Wolfwatching* (1989). He became Poet Laureate in 1984. He was preceded in this office by Sir John Betjeman, and succeeded by Sir Andrew Motion.

Marriage to Sylvia Plath

Hughes was married to the American poet Sylvia Plath from 1956 to 1963, when she committed suicide, and his controversial relationship with her has been the subject of several books, including his own poetic sequence, *Birthday Letters* (1998), which has been hailed as one of his finest works. He also produced a number of acclaimed children's books and versions of classical works, including *Tales from Ovid* (1997) and *The Oresteia* (1999).

LATER TWENTIETH-CENTURY DRAMA

Angry Young Men and Kitchen Sink Drama

The 1950s saw the emergence of a drama that turned away from the middle-class social worlds that had dominated the English stage in the middle of the twentieth century, in such plays as Sir Terence Rattigan's *The Browning Version* (1948) and *Separate Tables* (1954), towards work that offered a broader range of perspectives. Jimmy Porter, the hero of the first major salvo in this theatrical revolution, John Osborne's *Look Back in Anger* (1956), emerged as an archetypal "angry young man", challenging what he sees as the smug values of an earlier generation. However, Osborne's subsequent plays, which include a nostalgic study of an ageing music hall performer, *The Entertainer* (1957), *Luther* (1961) and *Inadmissible Evidence* (1964), failed to sustain the challenge. Osborne subsequently returned to the character of Jimmy Porter in *Déjà Vu* (1992).

Unlike Osborne, who had received a public school education, Arnold Wesker was born and brought up in a working-class milieu, in London's East End.

This provides the subject-matter for his more obviously proletarian trilogy, *Chicken Soup with Barley* (1958), *Roots* (1959) and *I'm Talking about Jerusalem* (1960) and plays such as *The Kitchen* (1959), while *Chips with Everything* (1962) drew on his experience in the RAF.

Set in working-class Salford, Shelagh Delaney's *A Taste of Honey* (1958), a play about a teenage single mother's relationships with her own irresponsible mother, the black sailor who fathers her child, and a gay art student who helps her with her baby, also brought new material onto the English stage. Written while its author was still herself a teenager, the play was first staged by Joan Littlewood's Theatre Workshop, a socialist company committed to broadening the repertory of English theatre and bringing drama to audiences that would not previously have frequented the theatre.

Other notable Theatre Workshop productions included *Oh What a Lovely War* (1963), a musical about World War I devised by Littlewood, which reflected changing attitudes to English society in the post-World War II period and remained popular during the years of protest against the Vietnam War.

Harold Pinter (1930–2008)

Harold Pinter's technically innovative plays also took British theatre into new territory. They are typically set in claustrophobic environments and, like such plays as Samuel Beckett's *Waiting for Godot* and Jean-Paul Sartre's *In Camera*, deal with bare, existential situations, in which characters appear to be grappling with undefined threats. Their enigmatic, laconic dialogue creates considerable dramatic tension, even as it obscures the possibility of narrative resolution.

His Rise to Prominence

Pinter first came to prominence as the author of *The Room* (1957). *The Birthday Party* (1957), *The Dumb Waiter* (1960) and *The Caretaker* (1960) established him as one of the most important figures among the new wave of British dramatists. His reputation was further consolidated by his screenplays for Joseph Losey's films *The Servant* (1963), *Accident* (1967) and *The Go-Between* (1970). Other major Pinter plays include *The Lover* (1963), *The Homecoming* (1965), *Old Times* (1971), *No Man's Land* (1975), *Betrayal* (1978) and *Mountain Language* (1988). His other film scripts include those for notable film versions of *The Caretaker* (1963), *The Birthday Party* (1967) and *The Homecoming* (1973) and the screenplays for several adaptations of novels including *The Quiller Memorandum* (1966), *The French Lieutenant's Woman* (1981) and *The Handmaid's Tale* (1990).

Sir Tom Stoppard (1937–)

Born in Assam of Czech parents, Stoppard is a dramatist, whose highly popular absurdist play *Rosencrantz and Guildenstern are Dead* (1966), in which minor characters from *Hamlet* await their call to action in a manner reminiscent of Beckett's *Waiting for Godot*, immediately established his reputation as one of the cleverest playwrights of his generation. Like his subsequent works, *The Real Inspector Hound* (1968) and *After Magritte* (1970), the play investigates different levels of theatrical reality. *Jumpers* (1972), in which a murder mystery, song and dance and philosophical discussion are brought together, and *Travesties* (1974), in which famous historical figures collaborate on a 1917 production of Oscar Wilde's *The Importance of Being Earnest*, are among his finest work.

Subsequent plays such as *Night and Day* (1978) and the one-act *Doggs Hamlet* and *Cahoot's Macbeth* (both 1979) move beyond the existential absurdism of his early work to demonstrate a greater concern with social issues. Stoppard's other plays include *Dirty Linen* (1976), *The Real Thing* (1982), *Hapgood* (1988), *Arcadia* (1993), *Indian Ink* (1995), *The Invention of Love* (1997), and *The Coast of Utopia*, (2002), a trilogy about nineteenth-century Russian revolutionaries.

His work for the cinema includes the screenplays for *Brazil* (1985), *Empire of the Sun* (1987), *The Russia House* (1990) and *Shakespeare in Love* (1998), for which he won an Oscar. He was knighted in 1997.

Other Dramatists of the 1960s and 1970s

Joe Orton became something of an icon for the Gay Liberation movement, after his early death in 1967 at the age of thirty-three. His plays, *Entertaining Mr. Sloan* (1964), *Loot* (1966) and *What the Butler Saw* (1969), are black comedies that blend Pinteresque menace with the traditions of more conventional farce to produce a unique postmodern mixture of the bizarre and the outrageous. Orton was murdered by his partner, the playwright Kenneth Halliwell, author of *Little Malcolm and His Struggle against the Eunuchs* (1965), who then took his own life.

Generally considered the most radical dramatist to come to the fore in the 1960s, Edward Bond achieved notoriety when his play *Saved* (1965) was banned, because of a scene in which a baby is stoned. Subsequently, his historical fantasy *Early Morning* (1968) suffered a similar fate. However, the seemingly sensational cruelty of Bond's early work can be seen as a Marxist critique of the deprivation of certain sectors of British society; and it expresses a viewpoint that became more prominent in the ensuing decades. His subsequent plays turn their attention to representing aspects of the literary heritage in equally controversial ways: *Lear* (1971) is a revisionist version of Shakespeare's *King Lear*, which shows the influence of the Theatre of Cruelty that had become popular in the 1960s and Bond returned to Shakespeare for *Bingo* (1973), a play about the Bard's last days. *The Fool* (1975) is a dramatization of the madness of the nineteenth-century poet, John Clare. Bond's other plays include *The Sea* (1973), *The Woman* (1978), *Restoration* (1981), *The Company of Men* (1992) and the television drama *Olly's Prison* (1993).

Dennis Potter (1935–94)

Dennis Potter established his reputation as one of the leading television dramatists with a play about a miner's son who becomes a parliamentary candidate, *Vote, Vote, Vote for Nigel Barton* (1965), and its sequel, *Stand Up, Nigel Barton* (1965). Beginning with *Pennies from Heaven* (1978), which follows the fortunes of a sheet-music salesman in the 1930s, he subsequently became better known for multi-part series that make highly effective use of popular music to express their protagonists' inner feelings, along with the spirit of the decades in which they are set. Like his subsequent series, *The Singing Detective* (1986), which is generally regarded as his most significant achievement, and *Lipstick on Your Collar* (1993), *Pennies from Heaven* uses its musical sequences as surreal counterpoint to the realism of the main action.

Potter's other work includes *Blue Remembered Hills* (1979), a nostalgic play about childhood set in the Forest of Dean where he grew up, and two further series that were screened after his death in 1994: *Karaoke* (1996) and *Cold Lazarus* (1996).

Sir Alan Ayckbourn (1939–)

Ayckbourn's reputation has been two-fold: as a major proponent of English regional theatre, who has been the guiding force behind the success of the Stephen Joseph Theatre in Scarborough; and as a prolific playwright, whose ostensibly light farces have received considerable acclaim through televised productions and on the West End stage. His fame as a chronicler of contemporary middle-class angst has grown steadily, to a point where it is possible to regard him as a major social commentator, though his theatrical milieu is a world away from that of the more obviously political dramatists of his generation. His plays include *Absurd Person Singular* (1972), the trilogy grouped under the title *The Norman Conquests* (1973), *Bedroom Farce* (1975), *A Chorus of Disapproval* (1984), *A Small Family Business* (1987), *Man of the Moment* (1988) and the two-part *House and Garden* (1999). He was knighted in 1997.

INTRODUCTION TO ART AND ARCHITECTURE

This popular section offers a concise introduction to some of the key terms, movements and styles in the history of art and architecture from ancient Greece to our own time. Terms included here range from Abstract Expressionism to Pop Art and from Neoclassicism to Socialist Realism. Readers may wish to refer to Section B for brief biographical details of major painters, artists, sculptors and architects.

PART I. THE WORLD OF ART

References to famous artists (indicated by *q.v.*) are to be found in **Section B, Prominent People**.

A

Aboriginal rock painting, colourful visual representations and engravings on rocks, ranging from hand or boomerang stencils to images of almost microscopic detail. It is often seen as the most original form of Indigenous Australian art. Made from water and spittle mixed with ochre and other rock pigments, this form of specific Australian art complemented the versions performed on other people's bodies or bark. It was used to mark territory, record history and tell stories recorded in the Dreamtime (*see* **J14**).

Abstract art designates paintings, prints or sculptures in which the subject-matter is simplified or schematised to a point that its representational qualities are subordinate to its form and colour. Examples include Cubism and Futurism (*q.v.*). The term is sometimes used loosely to indicate non-objective (*q.v.*) painting.

Abstract Expressionism, a term embracing a diverse group of artists (including Jackson Pollock and Willem de Kooning) working in New York during the 1940s. Their work emphasised the precedence of the creative process over the finished product, giving rise to the name Action Painting (*q.v.*). Although not an organised movement. Abstract Expressionism was influential in Europe and America. It changed the face of art for ever.

Academy, an official institution concerned with the training of artists and/or the promotion of art. Academies were initially a means of raising the social status of the artist, and they were often under aristocratic or royal patronage. The first art academies in Florence (founded 1563) and Rome (founded 1593) influenced the foundation of other academies throughout Europe in the seventeenth and eighteenth centuries, including France (1648) and England (1768), and in America in the nineteenth century. Academies were increasingly governed by a rigid set of hierarchies and a stultifying training programme, but they nevertheless exerted great influence in Europe and America until the mid-nineteenth century, when excluded artists (such as the Impressionists, *q.v.*) actively rebelled against their authority.

Action Painting is often used synonymously with Abstract Expressionism (*q.v.*), but it refers primarily to a method employed by artists such as Jackson Pollock. It involves applying paint to a canvas in a spontaneous manner, by allowing it to drip or splash. The term suggests that the process of painting itself is the primary concern of the artist.

Aerial perspective, or atmospheric perspective, refers to a sense of depth created by gradations of colour, rather than by the strictly mathematical formulas of perspective (*q.v.*). From the seventeenth century, much landscape painting, including that of Claude (*q.v.*) and Turner (*q.v.*) relies on this method.

Aesthetic Movement does not refer to an organised group of artists. It classifies a general cultural tendency in art, literature and interior design in late nineteenth-century England and, to a lesser extent, America, which encompassed a fascination for morbidity, decadence and sexuality. This cultivation of amorality included the idea of "art for art's sake", which allowed art to exist apart from any moral or didactic purpose. Oscar Wilde (*q.v.*) was the movement's most famous exponent, and the artists James MacNeill Whistler (*q.v.*) and Aubrey Beardsley (*q.v.*) were also considered "Aesthetes".

Aesthetics is a branch of philosophy concerned with concepts of art and beauty. The term was coined in the eighteenth century when the questions of how people perceive art and why they respond to it were considered by theorists such as Johann Joachim Winckelmann, Gotthold Ephraim Lessing (*q.v.*) and Immanuel Kant (*q.v.*).

Agitprop, agitational propaganda art, used to disseminate communist ideas and manipulate ideological beliefs, particularly by the Communist Party in Bolshevist Russia (later the Soviet Union) following the 1917 Revolution. Based on a combination of rational and emotional appeal and initially focused on the re-enactment of representative moments leading to the establishment of the "dictatorship of the proletariat", agitprop had a variety of manifestations. It ranged from conventional artistic forms to "agit-trains" and "agit-boats"—educational and publicity vehicles meant to take the Revolution to the remotest corners of Russia through showing films of Lenin and Trotsky, very explicit theatrical performances, manifestoes and pamphlets. Later in the western world the term acquired negative connotations associated with extreme left-wing political orientations that recalled those of communist Russia.

Alla prima, Italian for "at first", is a method of oil painting which involves applying paint in one session. By avoiding the contrivance of preliminary underdrawing or underpainting, the artist can achieve by this method a sense of spontanaeity. This technique was favoured by the Impressionists (*q.v.*).

Altarpiece, an object placed on or behind an altar, usually in a church. Altarpieces generally contain painting or sculpture and devotional or Biblical scenes, which are intended to enhance the spiritual experience of the worshipper. The subject-matter of altarpieces usually consists of images of the Madonna and Child with saints and/or donors (**N6**), or scenes from the life of the Virgin or Christ.

Alto-Relievo (high-relief), a term applied to sculptured designs which are depicted in prominent relief on a flat surface, technically signifying that the projections exceeds one-half the true proportions of the objects represented. **Basso-relievo** (low-relief) is carving kept lower than one-half such projection.

American Scene Painting, the realist, anti-modernist style of painting that spread in United States mainstream art during the Great Depression and aimed at defining an American art style in reaction to modernism, which was seen as a European import. The term is believed to derive from Henry James's 1907 book of essays and impressions *The American Scene* and encompasses two main schools within the movement: Regionalism (depicting rural scenes from an idealised nationalist perspective) and Social Realism (focusing on urban scenes). The main representatives are Charles Burchfield and Edward Hopper.

Antipodeans, a group of Australian painters (including Arthur Boyd and John Perceval) consecrated by an exhibition in Melbourne in 1959, with a manifesto written by the art historian Bernard Smith that stated the aesthetic superiority of figurative art over abstraction. The *Antipodean Manifesto* was to a great extent a reaction against the exhibition *The New American Painting* that toured Europe in 1958–59, championing abstraction.

Aquatint is a process of engraving which produces tonal effects similar to those of watercolour. It was especially common in England from the late eighteenth century for topographical views, and it has since been used to different effect by such artists as Goya (*q.v.*) and Picasso (*q.v.*).

Armory Show, an exhibition held in a Regimental Armory in New York in 1913. The presentation of over 1000 works included Impressionism (*q.v.*), Post-Impressionism (*q.v.*) and contemporary European and American painting. It had a radical impact on the development of American modern art.

Art Brut was the name given by Jean Dubuffet to the art of schizophrenics, prisoners and other individuals producing art outside the official and formal institutions and training traditions of the art establishment. Dubuffet believed that such "unsweetened" or untrained art was superior to the contrived and socially controlled productions of "fine artists". In English it is often referred to as "Outsider Art", the title of a 1972 book by Roger Cardinal.

Art Deco, the name given by modern collectors to the decorative style of the 1920s and 1930s; it is derived from the long official name of the Paris Exhibition of 1925, which was almost exclusively devoted to "les Arts Décoratifs". Art Deco runs parallel in time with Functionalism (*q.v.*) but unlike that austere and philosophical style, Art Deco is gay, elegant and even frivolous, being a creation of fashionable Paris. It is related superficially to Cubism, using squares, circles and triangles in interesting combinations for ornament. Another popular motif is the modern girl with her shingled head dancing the tango or drinking cocktails. The style is brash and worldly, but in its best expressions full of charm and vitality. Famous names within the style are the glassmaker Rene Lalique (1860–1945), the fashion designers Gabrielle Chanel and Elsa Schiaparelli, and the decorator and illustrator Erte (Roman de Tirtoff, b. 1829).

There was a revival of Art Deco, in films like "Bonny and Clyde" (1967) or "The Great Gatsby" (1974).

Art Nouveau (German *Jugend Stil*) was prevalent in architecture and decoration in Europe and the USA *c*, 1885–1910. It was rooted in the thoughts of Ruskin and William Morris and Pre-Raphaelite and Symbolist art. In reaction against the impersonal uniformity of industrial products which were flooding the market, artists turned to Nature for their inspiration, choosing organically growing forms, flowers or animals, as motifs for decoration or even for shaping whole objects. Another favourite motif was Romantic Woman with long robes and flowing hair, as interpreted so beautifully by Aubrey Beardsley. The sharply undulating line with a whiplash rhythm is a recurring theme. Famous names are the glassmakers Emile Gallé in France and Louis Comfort Tiffany in New York, the English goldsmith Charles Robert Ashbee (1863–1942), Henry Van de Velde (1863–1957) in Belgium and Charles Rennie Mackintosh (1868–1928) in Scotland, both architects and interior decorators, and in pure architecture Antonio Gaudí of Barcelona (1852–1926) and Victor Horta of Brussels (1861–1947).

Arte Povera literally translates "impoverished art", and it was a term invented by the Italian art critic Germano Celant in the 1960s. It refers to a disposable and Minimal (*q.v.*) art composed of perishable and easily accessible items such as sand and newspaper. Its premise was to detach art from market forces by stripping it of its consumer value, although ironically *Arte Povera* now fetches high prices. Its adherents include Michelangelo Pistoletto and Mario Ceroli.

Arts and Crafts Movement, the English revival of decorative art encouraging individual skill and the proletarian work ethic which began about 1875 as a revolt against the existing vulgarity of internal decoration and furnishings and the pettiness of academic art. Inspired by William Morris and Burne-Jones together with Rossetti, it was strongly influenced by the former's mediaevalism, his hatred of industrialism, and his own version of socialism which included the regeneration of man by handicrafts. His firm of Morris & Co. produced wallpapers, tapestries, furniture, stained-glass windows, carpets and fabrics in a style totally different from that of contemporary Victorian decoration. Morris's Kelmscott Press did much to raise the standards of book design and printing. *See* **Art Nouveau** (above).

Ashcan School, a name given retrospectively to a group of American artists who explored similar themes of city life between *c.* 1908 and the First World War. The original group was dominated by Henri Bellows, but it was later extended to include artists such as Edward Hopper. The name "ashcan" referred to the city dust-bins and thus evocatively defined the group's interest in the supposedly ugly side of city life.

Assemblage is a term, coined by Jean Dubuffet in 1953, often used to define a work of art which has been constructed from a variety of found (*q.v.*) materials. It is the three-dimensional equivalent of collage (*q.v.*).

Atelier is the French word for studio, but it refers more specifically to nineteenth-century studios in which a nude model was provided for artists to paint. This type of informal setting was also called an *atelier libre* (free studio), because unlike official art schools, it was open to all. Somewhat confusingly, *ateliers* were also known as academies (*q.v.*), the most notable of which was the Académie Julian, where Matisse (*q.v.*) studied. Although professional artists usually provided tuition, *ateliers* often worked without instructors.

Attribution, a claim that a work is by a specific artist, based on stylistic and documentary evidence.

Automatism is the process of producing a work of art or literature "automatically", or without the intervention of conscious thinking. It was favoured by Surrealist (*q.v.*) artists, who felt that they could use it to tap important subconscious thoughts. Joan Miró and André Masson used this technique most effectively, but only as a starting point for a work of art. The Abstract Expressionists (*q.v.*) embraced automatism more wholeheartedly, especially through Action Painting (*q.v.*).

Avant-garde is generally used in reference to art of the late nineteenth and early twentieth centuries, although it is employed loosely for other innovative periods of art history as well. It indicates art which is perceived as "progressive" or which challenges conventions or traditions. The concept helped perpetuate the Romantic notion of the elite artist as an individual working in opposition to inherited tradition.

B

Baldacchino (baldachin), a canopy placed over a throne, an altar or a holy place, such as the location of a saint's relics. Although it could sometimes be a moveable object in holy processions, it was usually a fixed part of a church, as in Bernini's elaborate *baldacchino* in St. Peters, Rome.

Barbizon School, a school of mid-19th-cent. landscape painters whose main tenet was a return to nature with an exact rendering of peasant life and country scenery painted on the spot. It was named after the village of that name in the Forest of Fontainebleau, where its chief members—Millet, Theodore Rousseau, Daubigny and Diaz—made their home. Their practice of painting direct from nature, made them the precursors of Impressionism (*q.v.*).

Baroque, a term used for the art style of the period *c.* 1600–1720 which was the artistic accompaniment of the Jesuit counter-Reformation. Its most obvious characteristics are: (*a*) its emotional appeal and dramatic intensity both related to its deliberate intention as propaganda ("a good picture makes better religious propaganda than a sermon" said one of its exponents); (*b*) in architecture, a style which is heavily and sometimes almost grotesquely ornate, plentifully covered with voluptuous sculpture on which draperies float rather than hang, with twisted and spiral instead of plain or fluted columns, and unnecessary windows or recesses added for ornament rather than use; (*c*) its emphasis on the whole at the expense of the parts such that a building's sculpture merges into its architecture and both into its painting (Baroque paintings are as closely knit as a jig-saw puzzle so that one cannot isolate individual figures as would be possible in a Renaissance one).

Baroque architecture owing to its origin is found mainly in the Catholic countries; Italy, France, Austria, Bavaria, *e.g.*, the Barberini Palace, Rome, designed by its greatest exponent Bernini and others; the Church of the Invalides, Paris. Baroque artists include Caravaggio, Guido Reni, Murillo and Rubens, the greatest Northern Baroque painter. The Baroque style merges gradually into **Rococo** (*q.v.*).

Bas-Relief. ("low relief"), a class of sculptures the figures of which are only slightly raised from the surface of the stone or clay on which the design is wrought.

Benin Bronzes, a collection of more than 1,000 brass plaques from the royal palace of the Kingdom of Benin, They were seized by a British force in the "punitive expedition" of 1897 and given to the British Foreign Office. Currently 200 of them are in the British Museum; others are in different collections and 50 were claimed by Nigeria, who bought them from the British Museum in the period from the 1950s to 1980s. The bronzes date back to the thirteenth to sixteenth centuries and depict animal scenes and scenes of court life. They were cast in matching pairs and served as mural decorations in the palace.

Biedermeier refers to German, Austrian and Scandinavian art produced between the time of Napoleon's defeat (1815) and the period of European revolutions (1848). Its name derives from a conflation of two characters in a satirical Munich magazine, and it is therefore meant to be slightly mocking or pejorative. It signifies a sentimental Realist (*q.v.*) style favoured by the increasingly prosperous middle classes, and practised by such artists as Ferdinand Waldmüller and Carl Spitzweg, especially in landscape and genre (*q.v.*) scenes.

Biomorphic forms are abstract shapes based on organic sources such as plants. In painting and sculpture, biomorphism became popular with Surrealist (*q.v.*) artists such as Yves Tanguy and Jean Arp, who exploited its sexually suggestive nature.

Bitumen is a brown pigment commonly used by English artists in the eighteenth and early nineteenth centuries. It contributes to the richness of a painting's tone, but it darkens and becomes opaque over time and causes chemical reactions which ultimately damage the paint surface. *See* **Craquelure**.

Black Mountain College, leading progressive American art school, active in North Carolina between 1933 and 1957, which encouraged an interdisciplinary, experimental, informal, collaborative approach to the arts and a tight connection between education and experience. Founded by former faculty of Rollins College led by John Andrew Rice, Black Mountain pushed the principles of Bauhaus further and emphasised the need to turn students' attention away from an idealisation of the cultures of Europe to their own immediate perceptions and skills. Many important American artists of the 1960s (such as John Cage, Merce Cunningham, Willem and Elaine de Kooning, Walter Gropius, Robert Motherwell, Robert Rauschenberg, Joel Oppenheimer *etc.*) taught at or were influenced by Black Mountain.

Blaue Reiter, Der (**the Blue Rider**) was a group of artists based in Munich who banded together in 1911 to challenge the academic conventions of contemporary art. Among their membership were Wassily Kandinsky and Franz Marc, who invented the name to signify their belief in the spiritual significance of horses and the colour blue. An interest in the "Geist", or the inner nature of man, governed their paintings and the themes of their only publications, the *Blaue Reiter Almanac* (1912). They sponsored two travelling exhibitions in 1912 and 1913 which brought together progressive tendencies in European art. Their interest in the spiritual qualities of line and colour made their work an important contribution to Expressionism (*q.v.*).

Bloomsbury Group, a group of British writers and artists most influential between *c.* 1910 and *c.* 1940. One of the members, Roger Fry (*q.v.*), organised the so-called "Post-Impressionist" exhibitions in 1910 and 1912 in which many works by Cézanne (*q.v.*), Manet, Van Gogh (*q.v.*) and Gauguin received their first English showing. Fry's insistence on the importance of colour and "significant form" influenced the work of Duncan Grant and Vanessa Bell and fostered an interest in decorative art best seen today in Grant's former Sussex home, Charleston.

Bodegón is Spanish for "tavern". In art, it refers to a type of genre painting (*q.v.*) set in a kitchen and including still-life detail. Velásquez (*q.v.*) produced several *bodegones* early in his career.

Body Art, art that uses the artist's body, rather than other materials, as its medium. Most often it consists of tattoos, body-piercing and body-painting. Most extreme forms, present in socially engaged art, include mutilation, self-inflicted pain and ritualistic acts of endurance in order to make strong anti-establishment statements. French artist Orlan in the 1990s is famous for using plastic surgery to produce body features based on Renaissance masterpieces and to protest against current standards of beauty.

Body art is closely related to conceptual art and performance art and was promoted by their flourishing in the 1960s and 1970s. Body art is not an exclusively western form: an influential source is eastern theatre, such as the kathakali dance-drama of Kerala, which uses exquisite make-up based on a complex colour code that contributes to the communication of meaning in the performance.

Bozzetto, Italian for "sketch", but, more precisely, a small-scale model for sculpture made in clay or wax, rather than a sketch for painting.

Brücke, Die (**the Bridge**), a German Expressionist group formed in Dresden in *c.* 1905. The four original members, Ernst Ludwig Kirchner, Erich Heckel, Karl Schmidt-Rottluff and Fritz Bleyl, were architecture students rather than trained artists, and they cultivated a crude, untutored style as a means of perpetuating their interest in non-European art. They had a strong social consciousness and hoped to foster changes in society through their art, although these ideas were never clearly articulated. Their most notable contribution was a revival of the woodcut (*q.v.*) technique. In *c.* 1911 several members of the group moved to Berlin, and Kirchner began painting scenes of city life which stressed claustrophobia and corruption. Internal dissension led to the dissolution of the group in 1913.

Brutalism, the term for the concrete edges and urban grey buildings of the 1950s and 1960s.

Burin, a hand-held steel tool used in engraving to cut into a metal plate. It is also called a graver. As it must cut directly into the plate, more forceful pressure is applied than is needed with an etching needle, which scratches into a resinous ground.

Burr. In engraving, a metal shaving remaining after a plate has been cut by a burin (*q.v.*). In line engravings (*q.v.*) the burr is scraped away, but in drypoint (*q.v.*) it is often left to create furry tonal effects in the print.

Byzantine Art developed in the eastern part of the Roman empire after Constantine founded the city of Constantinople (A.D. 330). It has many sources—Greek, Syrian, Egyptian and Islamic — and reached its zenith in the reign of Justinian (527–65). The major art form was ecclesiastical architecture, the basic plan of which was Roman—either basilican (symmetrical about an axis) or centralised (symmetrical about a point). Arched construction was developed, and the dome became the most typical feature, although, unlike the Roman dome which was placed on a round apartment, the Byzantine dome was placed on a square one on independent pendentives. Frequently small domes were clustered round a large one as in the case of the great church of Santa Sophia (537), the climax of Byzantine architecture. Usually the churches were small and include those of SS. Sergius and Bacchus, Sta. Irene (in Constantinople), S. Vitale in Ravenna, and the much later and larger St. Mark's in Venice.

Byzantine art also took the form of miniatures, enamels, jewels, and textiles, but mosaics, frescos, and icons (*q.v.*) are its greatest treasures.

C

Cabaret Voltaire was the night club in Zürich in which the European Dadaism (*q.v.*) movement began. During the First World War, artists and intellectuals who were pacifists or dissenters gathered in neutral Switzerland. Among this group, Tristan Tzara, Jean Arp and Hugo Ball staged a series of events at the Cabaret Voltaire in 1916 which were intended to express their outrage at the futility of modern life and the chaos of war.

Cabinet pictures, small paintings originally intended to be hung in the limited confines of seventeenth-century Dutch bourgeois interiors. These paintings consisted primarily of still-life, landscape or genre (*q.v.*), and their emergence in seventeenth-century northern Europe signalled the new importance of a wealthy art-buying middle-class.

Camden Town Group, an organisation of English artists who broke from the New English Art Club (*q.v.*) in *c.* 1911. Following the example of Sickert's (*q.v.*) works, Harold Gilman, Charles Ginner and Spencer Gore concentrated on painting the ordinary or even ugly aspects of London life. The group was characterised by a common enthusiasm for Post-Impressionism (*q.v.*), which they helped to popularise in England.

Camera obscura, Latin for "dark chamber", is a dark box in which an image is projected through a lens to allow artists to copy it easily. A precursor of photography, the camera obscura was used by such artists as Vermeer (*q.v.*) and Canaletto (*q.v.*) to facilitate a sense of spatial illusion and accuracy in their works.

Caricature, a portrait in which characteristic features are exaggerated or distorted to produce a comic effect. The first are thought to have been made in seventeenth-century Italy by Annibale Carracci. Caricature was popular in eighteenth- and nineteenth-century England, where it became a vehicle for political satire in the hands of James Gillray (*q.v.*) and George Cruikshank (*q.v.*).

German artists such as George Grosz and Otto Dix produced a more vicious form of political and social caricature during the 1920s.

Cartoon today signifies a comic strip or children's animation, but in the sixteenth century, it referred to a preparatory drawing which was the same size as the finished work and which was used to plan out the work itself. Raphael's cartoons for tapestry (now at the V&A Museum, London) are the most famous extant example.

Cassone, Italian for "coffer" or "chest". In fifteenth- and sixteenth-century Italy, cassoni were used for marriage chests, and they were richly, if sometimes crudely, painted, usually with a mythological scene containing a theme of love or marriage.

Cave Paintings are the oldest forms of art to survive. Among the most famous are those at Lascaux in the Dordogne in France. The 17,000 year-old paintings (known as the "Sistine Chapel of Prehistory") feature deer, lions, horses and other animals. These paintings are now threatened by bacterial and fungal infection. Other paintings in the Dordogne, found in 2007, date back 37,000 years. Cave art found in NW Spain dates back 40,800 years. Exciting new cave art was discovered in 2016, in the Basque town of Lekeitio. Women played an important part in these early paintings. Cave paintings in Indonesia are as old as any found in Europe.

Chiaroscuro (Italian "clear-dark"), a term used in painting to denote the disposition of light and shade. Rembrandt is unrivalled as a painter for his contrasts of light and shadows.

Chinoiserie, European decorative designs based on Chinese ornamentation. Chinoiserie was fashionable during the Rococo (*q.v.*) period, especially prevalent in decorative arts, landscape gardening and architecture.

Chromolithography, a type of colour lithography (*q.v.*) in which a separate plate is used to print each colour.

Classicism, like its derivatives "classic" and "classical", is a term often used loosely and inaccurately to refer to the best example of a period or style. In its strictest sense, it signifies an emulation of ancient Greek or Roman art, or the conscious attempt to recall the order and harmony associated with ancient sculpture and architecture. *See* **Neo-classical style**.

Cloisonnism is used to describe the style adopted by Gauguin in the 1880s. It refers to the use of large patches of colour surrounded by outlines, which recall the effects of stained glass windows. The term originally referred to enamel painting.

Collage (from French "*coller*", to stick) objects such as newspaper, string or cloth which are pasted onto paper or canvas. Although it had long been an amateur pastime, this technique was first employed seriously by Picasso (*q.v.*) in *Still Life with Chair Caning* (1912), which signalled a move away from his Analytical Cubist works, towards the creation of Synthetic Cubism.

Collage was also later used satirically or humorously in the works of the German Dada (*q.v.*) artists, such as George Grosz and Kurt Schwitters, and for its startling juxtapositions in the works of Surrealists (*q.v.*) such as Max Ernst.

Colour Field Painting was a style of abstract painting prevalent in America during the 1950s and involving artists such as Barnett Newman, Mark Rothko and Clifford Still. Although included under the umbrella of Abstract Expressionism (*q.v.*), these artists were concerned more with large expanses of pure colour than with the Action Painting (*q.v.*) technique of other Abstract Expressionists such as Jackson Pollock.

Column, in architecture, is an upright solid body serving as a support or decoration to a building. Columns consist of a pedestal, a shaft, and a capital, over which the supported entablature rises. They are named according to the styles of architecture of which they form part, *e.g.* Doric, Tuscan, Ionic, Corinthian or Composite .

Complementary colours are green, orange and violet. They are produced when two primary colours (*q.v.*) are mixed together. Green is the complementary of red as it is produced by mixing blue and yellow; blue is the complementary of orange, and violet is the complementary of yellow.

Conceptual Art is a product of the late 1960s. Artists rejected traditional methods of producing and displaying art, and relied instead on photographs, videos and language to take the place of easel painting. In Conceptual Art, the idea is more important than the finished product.

Concrete Art, an autonomous form of abstraction that avoids all figurative reference and symbolical associations with reality and argues that lines and colours are concrete in themselves, It evolved from De Stilj, futurism and Kandinsky's abstract use of colour and geometrical shapes. The term was coined by Theo van Doesburg, whose Abstraction-Creation group in Paris was dedicated to the establishment of this art form in the 1930s.

The Swiss painter Max Bill continued it beyond World War II. Concrete Art led to Minimal Art and Op Art.

Constructivism, a Russian art movement initiated by Vladimir Tatlin in *c.* 1913. After visiting Picasso (*q.v.*) in Paris, Tatlin returned to Russia with the idea that a "culture of materials" could result in an art which had social purpose. However, subsequent Constructivists were divided between the concept of art as utilitarian and the idea that art should be pure form. The Russian Revolution in 1917 gave the movement new impetus, but it was condemned by the Soviets in 1922 and then spread exclusively in Western Europe.

Contrapposto is usually used in relation to Italian Renaissance painting and sculpture, although it has been applied more widely. It refers to a twisted torso posture which creates an elegant S-curve. Used most effectively by Michelangelo (*q.v.*) in his *David*, contrapposto became more elaborate and virtuosic in the hands of Mannerist (*q.v.*) artists such as Giambologna.

Conversation piece, an informal group portrait, usually of a family or friends. Its precedents are in Dutch seventeenth-century group portraiture, but it became more popular in eighteenth-century England through the work of such artists as William Hogarth (*q.v.*) and Johan Zoffany. Conversation pieces usually showed a family or friends in a domestic interior or standing before a country seat, and they gave the effect of cultivated informality.

Craquelure, the pattern of cracks on the surface of a canvas when the paint deteriorates.

Cubism, the name of a revolutionary movement in art created by the two painters Picasso and Braque and prominent in France between 1907 and 1914. Rejecting purely visual effects, they approached nature from an intellectual point of view, reducing it to mathematical orderliness. Its respectable grandparent was Cézanne who had once written: "you must see in nature the cylinder, the sphere, and the cone"—a concept which, together with the contemporary interest in Black sculpture, moved the two founders of the movement to experiment with the reduction of natural forms to their basic geometrical shapes. In practice, this meant combining several views of the object all more or less superimposed in order to express the idea of the object rather than any one view of it. The name Cubism was derisive and the movement aroused the same opposition as Impressionism, Fauvism and the later Futurism. Picasso's *Les Demoiselles d'Avignon* (1907; Museum of Modern Art, New York) was his first painting that announced the emergence of Cubism. Three phases are recognised: (1) Cubism under the influence of Cézanne; (2) high or analytical Cubism (*c.* 1909– 12) concentrating on the breaking-down of form to the exclusion of interest in colour; (3) synthetic Cubism (*c.* 1913) making use of *collage* in which pieces of pasted-on paper (illustrations, wallpaper, newspaper) and other materials were used in addition to paint.

Amongst other early Cubists were such figures as Metzinger, Gleizes, Gris and Léger.

D

Dadaism (French *Dada* = hobby-horse) was an eccentric and nihilistic precursor of **Surrealism** (*q.v.*) resulting from the shock produced by the first world war. Beginning in Cabaret Voltaire (*q.v.*) Zurich about 1915, it spread to other continental cities, such as Berlin and Paris, dying out in 1922. The movement was deliberately anti-art, destructive, and without meaning; it intended to scandalise by such tricks as "compositions" made out of anything that came to hand—buttons, bus tickets, pieces of wire, bits of tin, *etc.* Other excesses included randomly ordered poetry, Dada night-clubs, plays, and short-lived newspapers. Many Dadaist painters became Surrealists at a later stage, but where Surrealism is a deliberate attempt to present dreamlike images, Dadaism was sheer anarchism and randomness. Leading Dadaists were Hans Arp, Marcel Duchamp, André Breton, Kurt Schwitters and Max Ernst.

Damaskeening, the art of inlaying one metal upon another, largely practised in the East in mediaeval times, in the decoration of sword blades.

Dau al Set (Catalan *The Seven-Spotted Dice*), an avant-garde association of Catalan artists (Joan Brossa, Arnau Puig, Modest Cuixart, Joan Ponç, Antoni Tàpies and Joan Josep Tharrats), upholding Surrealist, existentialist and Marxist views, founded in Barcelona in 1948. The association published a periodical of the same name, which suggested pushing artistic experimentation beyond expected limits (since six is the maximum number of spots on the side of a dice). The periodical continued until 1956 with some changes in format. It played an important part in rejecting the political establishment and promoting avant-garde artistic thinking in Spain.

Decalcomania (French *décalcomanie*, from *décalquer*, "to transfer" and *manie*, "mania"), a decorative technique of transferring images (engravings and prints) from one surface to another, which is believed to have been invented by the Spanish Surrealist Oscar Domínguez in Paris in 1935. The technique consisted of covering a sheet of paper with splashes of paint that were then covered with another sheet and rubbed gently, producing fantastic shapes and effects free from the prejudice of any subject or form. Decalcomania was widely used by Max Ernst in painting and by Richard Genovese in photography.

Degenerate Art (**Entartete Kunst**), the name given by Adolf Hitler (*q.v.*) to art which he felt was produced by Marxists or Jews and/or which had a negative subject-matter that did not glorify the German people. He contrasted "Degenerate Art" with his favoured brand of Nazi realism, which idealised German Aryan character and culture.

The contrast between these two forms was highlighted in 1937, when a "Degenerate Art" exhibition and a "German Art Exhibition" were held simultaneously in Munich. After these exhibitions, the "degenerate" paintings were either sold to raise money for Germany or destroyed. This label encompassed the art of most modern movements, particularly Expressionism (*q.v.*).

Diorama, a type of large painting invented by Daguerre in 1822. Like the panorama (*q.v.*), the diorama contained effects of atmosphere which were achieved by using translucent canvas, movement and special lighting. Three-dimensional elements, such as real plants or animals were also employed to make the effects of dioramas more convincing. Dioramas were an accessible form of public entertainment in the early nineteenth century.

Diptych can refer to a type of altarpiece created when two panels are hinged together. Unlike triptychs (*q.v.*) and other polyptychs (*q.v.*), diptychs were often small and used for private devotional purposes in the Middle Ages.

Divisionism, the name given to the theory developed by Seurat and others, which suggests that colour placed on a canvas in unmixed dots will give the optical effect of being mixed. The technique of Divisionism has also been called pointillism (*q.v.*) or Neo-Impressionism (*q.v.*). Divisionism also refers to an Italian art movement of the late nineteenth and early twentieth centuries in which such an application of colour is employed.

Donor, a person who has given an altarpiece (*q.v.*) or other devotional image to a church as a means of securing God's grace. The term is most appropriately applied to late Medieval and early Renaissance art in Italy and the North. Artists such as Jan van Eyck and Hugo van der Goes included portraits of donors in their altar-pieces.

Drip painting, a technique used by Jackson Pollock and other Abstract Expressionists (*q.v.*) which involves applying paint not with a brush but through other methods (*e.g.* dripping or splashing).

Drypoint, an engraving (*q.v.*) technique used from the late fifteenth century which is similar to etching in its method. To make a drypoint, a copper plate is cut directly, producing a burr (*q.v.*), which softens the tonal effect. This technique is often used in combination with others, but it has the disadvantage of producing only a limited number of impressions, before the burr is worn away.

E

Earthwork (**Land Art**), a dispersed tendency in art of the late 1960s, which involved using large expanses of natural spaces. Earth art employs the landscape for artistic purposes and thus opposes the sophisticated industrialisation of city culture. Examples of this genre, such as Robert Smithson's *Spiral Jetty* (1970), need to be seen from aircraft or by means of photography.

Embossing, the art of stamping in relief, letters or designs upon pliant substances.

Empire, the style created in France during the reign of Napoleon in architecture and all the arts. It is austerely classical, making much use of columns, pediments and the like in buildings as well as furniture, with eagles and sphinxes, reminiscent of Napoleon's campaigns, as ornaments. The style is heavy, grandiose and with a strong element of the heroic. A typical monument is the *Arc de Triomphe* in Paris (begun 1806), almost a repetition of a Roman model. In painting Jacques Louis David interpreted the style with heroic subjects taken from mythology or from Napoleon's career. The style was transmitted to the rest of Europe.

Encaustic, an ancient technique of painting in which pigments are submerged in soft hot wax. Examples of the encaustic process can be seen on Egyptian mummy cases. Despite the allure of the technique, there have been very few successful attempts to revive it through the centuries.

Engraving is the art of cutting, incising or otherwise forming designs of pictures on wood, stone, or metal surfaces for reproduction by some method of printing. Wood-engraving was the earliest in the field, dating from the 15th cent. Later, engraving on steel and copper plates was introduced, and mezzotint (*q.v.*), lithography (*q.v.*), stipple, aquatint, *etc.* Most modern methods of reproduction are based on photography.

Entablature, that portion of a building which surmounts the columns and extends to the roof of the tympana of the pediments; it comprises the architrave, the frieze and the cornice.

Environmental Art, art form based on the creation of a three-dimensional space in which the spectator can be completely enclosed and subject to a set of multiple sensorial (visual, kinetic, tactile and even olfactory) stimuli. It is characteristic of some of the surrealist experimentation of the 1920s and 1930s, but developed as a movement in the 1950s and 1960s in close connection with "happenings". More recently the term has also been used to refer to art concerned with ecological issues or which aims to protect the environment

Etching, a print technique in which an acid resistant ground is cut by a thin metal pencil. Parts of the plate are then "stopped out" or covered with a protective material, and the plate is dipped into acid which eats away at the exposed areas. The technique is simpler and more spontaneous than engraving (*q.v.*) and produces more convincing tonal gradations.

Euston Road School, a group of artists who studied together in the late 1930s at the School of Drawing and Painting on Euston Road in London. The group included William Coldstream, Lawrence Gowing, Claude Rogers and Victor Pasmore, and they rejected Modernist abstraction and Surrealism (*q.v.*) in favour of a return to an impressionistic rendering of everyday life.

Expressionism, a modern art movement confined primarily to the non-Latin countries of Europe which sought to give expression to strong intimate and personal emotions by means of distortions of line and colour and simplified style which carried a greater impact in terms of feeling. Broadly speaking, this has been characteristic of northern art in general. (*See* **Gothic**).

The term is usually used of the modern movement which influenced the Post-impressionists and subsequent movements in France. Tired of the naturalism of the Impressionists, such artists as van Gogh, Gauguin, Matisse and Rouault, together with the Fauvists (*q.v.*) made use of simple outlines and strong colours.

Apart from Toulouse-Lautrec, the principal Expressionists were Norwegian, like Munch, or German, like the painters of *Die Brücke* and *Der Blaue Reiter* groups. Individual artists were Ensor, Kokoschka, Nolde, Rouault and Soutine. *See also* **Blaue Reiter, Der** and **Brücke, Die**.

Exquisite corpse (French *cadavre exquis*), a game consisting of the collective making of a sentence or an image by a group of people and folding the paper on which it has been written to cover what has been done so far so that no member of the group is aware of what the others have contributed. In the case of drawing, the end of each part was left visible so that the next player could start from it, without being aware of its original meaning. It was favoured by Surrealists (André Breton, Yves Tanguy *etc.*) as a way of exploring the depths of the unconscious or the role of chance in creation.

F

Fan Tracery, a complicated style of roof-vaulting, elaborately moulded, in which the lines of the curves in the masonry or other material employed diverge equally in every direction. It is characteristic of the late Perpendicular period of Gothic architecture, and may be seen in St. George's Chapel at Windsor and the Chapel of Henry VII at Westminster Abbey.

Fancy picture is a vague term, usually used to define late eighteenth-century English paintings with fanciful subject matter. Gainsborough's (*q.v.*) idyllic evocations of rural life and portraits of winsome "peasant" children were given this name by his critics. Fancy pictures, unlike genre (*q.v.*) paintings, are not concerned with the mundane aspects of daily life.

Fauvism (French *Fauve* = wild beast), a term used, at first contemptuously, to describe the work of a group of French painters who first exhibited at the Salon d'Automne in Paris in 1905. The most prominent among them was Henri Matisse. Forms are freely distorted and colours are selected and applied for their emotive power with no necessary reference to the "real" colour of the object in question. Other famous *Fauves* were Derain, Vlaminck and Rouault. By 1907 the group was fading and by 1908 its members went their separate ways.

Federal Art Project (FAP), a project designed to employ and promote artists through the Depression years in the United States, which ran between 1935 and 1943 as part of President Franklin D. Roosevelt's New Deal. Directed by Holger Cahill, a museum administrator and expert in American folk art, the project employed artists to decorate public buildings, produce posters, prints, murals and various other craft works and set up community arts centres and galleries in parts of the country where there was virtually no artistic activity. The project aimed at stimulating artistic production, instruction and research and is famous for having produced more than 200,000 separate art works.

Feminist art history, a movement in art-historical scholarship since the late 1960s, prompted by the Women's Liberation Movement, which involves a reassessment of both women artists and of how women were and are perceived in art. Feminist art history challenges the canon of male "genius" artists by questioning the male dominance of art academies and art criticism. Such dominance has caused both the exclusion of women from professional art training and the relegation of women to the subject-matter of painting, or merely the object of male desire. Feminist art history has also been concerned with conflicting problems of gender and class, and with sexual theories, including those of Freud.

Fête galante, or "courtship party", was a name given to the paintings of the French artist Watteau (*q.v.*) in the early eighteenth century. It refers to a number of courtly paintings by him which show groups of men, women and characters from Italian theatre.

Fontainebleau, School of indicates two "schools" of sixteenth-century European art. The first of these originated in the 1530s, when the French king, Francis I, hired Italian artists to decorate his new palace at Fontainebleau. Artists such as Rosso Fiorentino and Niccolo dell'Abbate produced an elegant, mannered style which was much imitated in painting, sculpture and the decorative arts. The second school of Fontainebleau was a later development of the first.

Foreshortening, a use of perspective to create an illusion of depth related to individual figures or objects, rather than space. Foreshortening was used during the Renaissance by artists such as Mantegna to show their command of illusionism.

Formalism, an approach to art in which the formal qualities of art work (line, shape and colour) are seen as instruments of meaning-production and prevail over representational, ethical and social considerations. Formalism has been central to the development of all forms of abstraction since the beginning of the twentieth century. Art critics such as Clive Bell and Roger Fry in Britain and Clement Greenberg in the United States were among the main promoters of such "pure" views in art criticism. They have been strongly opposed by supporters of the idea that form and content must go together and that art must always provide some kind of representation of reality.

Found object (objet trouvé) refers to a natural or man-made object which is displayed as a work of art. Found objects are not made by artists, but artists sometimes use them as a starting point for a creative idea. They were particularly used by the Surrealists.

Fresco, a painting executed upon plaster walls or ceilings, a technique which has remained unchanged since it was practised by the great Renaissance artists.

Frottage, a technique employed by Surrealist (*q.v.*) artists such as Max Ernst, which involves placing a piece of paper over an object and rubbing the paper with chalk or charcoal. The impression left on the paper was used as a starting point for a work of art.

Functionalism, in architecture, a movement originated by Le Corbusier, Swiss-born French architect and town-planner, who applied the austere principles of the Purist movement in painting to his own art. From about 1924 he designed in concrete, steel and glass, buildings in which every part had a significance in terms of function on the theory that objects created to carry out their particular function to perfection cannot help being beautiful. "A house is a machine for living in." The style was in vogue between the two wars and it is still very much used.

Futurism, an Italian school of art and literature initiated by Marinetti, an Italian writer and mountebank friend of Mussolini at a later period. Its origin took the form of a manifesto published in Paris in 1909 in which Marinetti glorified violence, war and the machine age. In its aggression it favoured the growth of fascism. One of the distinctive features of Futurist art was the use of the principle of "simultaneity" in which the same figure (*e.g.*, a woman descending a flight of stairs) is represented in successive positions like film "stills" superimposed on each other. In spite of two further manifestoes it was not until 1911 that the first examples of Futurist painting and sculpture appeared by the artists Severini, Balla and Boccioni. Apart from the principle of simultaneity, Futurism derived from Cubist and Post-impressionist techniques. The movement faded out in the first world war.

G

Genre means literally "type" or "kind", and it signifies the painting of ordinary people or everyday life. Various genre details began appearing regularly in fifteenth and sixteenth-century Netherlandish painting, the most notable examples of which are Pieter Bruegel's peasant subjects. Genre painting became a distinctive class of painting in seventeenth-century Holland, when a prosperous middle-class preferred such accessible images to abstruse historical subjects.

Gesso (Italian "chalk"), an absorbant ground (*q.v.*) used in Medieval and also Renaissance panel painting. Several layers of gesso were laid onto a surface before the paint was applied. Its brilliant white colour added to the luminosity of these paintings.

Giralda, a beautiful and remarkable surviving example of Arabian art, erected in the late twelfth century at Seville.

Glasgow School refers both to the "Glasgow Boys" and to the followers of Charles Rennie Mackintosh's art nouveau (*q.v.*) style. The former was a group of Scottish painters influenced by Whistler (*q.v.*) and the French Impressionists (*q.v.*) and flourishing in the 1880s and 1890s.

Glaze, a thin transparent layer of paint put over the canvas surface to create a luminous effect. Because the glaze is transparent, it allows layers underneath to shine through.

Gouache, a type of watercolour in which the paint is dense and opaque, rather than transparent. It was used commonly in medieval manuscript illumination (*q.v.*), but was less popular for topographical watercolours produced in the eighteenth and nineteenth centuries. It is also known as body colour.

Graffiti Art derives from the vandalistic urban practice of applying images or letters with a spraycan on walls without permission and is hence also called Spraycan art or Subway art. It is particularly related to a trend in New York in the 1980s, consecrated artistically by the opening of the Museum of American Graffiti in 1989. Representatives were Jean-Michel Basquiat, who took street art into the mainstream, and Keith Haring, who painted graffiti-inspired cartoon-like images. Graffiti is an expression of dissident art.

Grand Manner refers to the elevated style associated with history painting (*q.v.*). It was discussed by Joshua Reynolds (*q.v.*) in his Royal Academy discourses of the late eighteenth century. Reynolds described the Grand Manner as an art which stressed general concepts as opposed to particular details.

Greek Art. *See* **Hellenic Art.**

Grisaille paintings are executed in grey or monochrome. They were often meant to imitate sculpture and were commonly used on the closed panels of altarpieces (*q.v.*) to create an austere image appropriate for Lent or fast days.

Ground, the substance placed on the surface of a canvas or panel on which the colours are painted. The ground comes between the canvas itself and the paint, and serves both to preserve the painting and create a more satisfactory visual effect.

Group of Seven, a group of Canadian landscape painters who exhibited together in the early 1920s and 1930s. It included Lawren Harris and A. Y. Jackson. Their aim was to create a specifically Canadian brand of modern painting, using familiar Ontario landscapes and an Expressionist (*q.v.*) colourism.

H

Happening, a seemingly spontaneous event, which takes on qualities of both art and theatre, although it is more ephemeral than art and less coherent than theatre. Coined by Alan Kaprow in the late 1950s the term is applied to art of the 1960s which involved performance and required the presence of an audience.

Harlem Renaissance, major African-American cultural movement based in Harlem, New York, whose main focus was literary, but which also included important artistic manifestations, as shown and encouraged by Alain Locke in his books *Negro Art: Past and Present* (1936) and *The Negro in Art* (1941). Harlem Renaissance artists, such as Aaron Douglas and Palmer Hayden, explored the ancestral heritage of black people in the US, tracing it back to its African sources.

Hatching, the use of parallel lines drawn or painted close together to create tonal effects. Cross-hatching refers to the use of crossed lines for the same purpose.

Hellenic Art. The art of ancient Greece may be roughly divided into three periods: the prehistoric period (*c.* 1600-1000 B.C.) of the bronze age Mycenaeans; the archaic period (*c.* 700-500 B.C.); and the classical period (*c.* 500-300 B.C.). Of the first period centred on Mycenae in Peloponnesus but extending to the coasts of Asia and the city of Troy we can mention only the massive stone gateways and the shaft graves of Mycenae, where the archaeologist Schliemann discovered painted vases, gold cups, bronze swords and ornaments of what had once been a great, if primitive, civilisation. During the archaic period sculpture was the principal form of art expression. The magnificent male and female figures are reminiscent of Egyptian art, but are distinctive in liveliness of facial expression. The vase-paintings of this period became more elaborate, depicting scenes from mythology or ceremonial events.

Typical of classical Greek art is the representation of the beautiful and healthy human body deliberately posed and often carrying out heroic or athletic acts. The vast majority of these statues are known to us only through Roman copies. The *Hermes* of Praxiteles (born *c.* 385 B.C.) is possibly the only existing statue which can be assigned fairly certainly to an individual artist.

Almost the whole of the Greek genius in architecture was expended on temples which are all basically similar in design—a rectangle with a low-pitched gabled roof resting on side walls. The three orders Doric, Corinthian and Ionic mainly referred to the type of column used, but naturally the whole building was influenced thereby. Some of the main buildings are on the Acropolis, a hill outside Athens, on which stand the Parthenon (from the outer frieze of which the Elgin marbles (*q.v.*), now mostly in the British Museum, were taken), the Erechtheum, famous for its Porch of Maidens, and the gateway known as the Propylaea with its broad flight of marble steps.

Apart from that on vases, no Greek painting has come down to us, although Greek painters existed and were noted in their time. All we have are copies in mosaic and fresco made by the Romans, at Naples and Pompeii.

Of Greek literature for the early period (*i.e.*, the archaic age) belong Homer's *Iliad* and *Odyssey*. Hesiod's long poem *Work and Days* and Sappho's love poems, and Pindar's Odes. The period of Pericles in the 5th cent. B.C. produced more great literature than any comparable period in history: the philosophical writings of Plato and Aristotle, the tragedies of Aeschylus, Euripides and Sophocles, the comedies of Aristophanes—all these are still part of the European tradition, and together with Greek architecture played a major part in the Renaissance.

Hellenistic Art, the age of the period of Greek civilisation which began with the conquests of Alexander the Great (356–323 B.C.) and lasted until his former empire (which encompassed most of the Middle East and part of North Africa) was conquered by the Romans in 146 B.C. Culturally it was an important period because it spread Greek culture far beyond its original boundaries—even as far as the north of India, and its centres spread from Athens to the cities of Alexandria in Egypt, Antioch in Syria and Pergamum in Asia Minor. But equally Eastern culture spread to the West: democracy was replaced by absolute monarchy, cosmopolitanism took the place of the Greek tendency to believe that all who were not Greeks were barbarians, and mystical philosophies took the place of Greek rationalism.

This was a sensuous, secular, pleasure-loving, rootless society, and these tendencies were reflected in its art.

Hellenistic sculpture was sensual, effeminate, excessive and violently emotional, depicting individuals and not always noble or beautiful ones. (Classical Greek sculpture was idealistic, showed types rather than individuals and appealed to the intellect rather than the emotions.) Some of the best examples came from the school at Pergamum and later from the island of Rhodes, and the titles themselves speak of their nature: *The Dying Gaul*, *Gaul Slaying his Wife and Himself* and the famous

Laocoön (representing Laocoön and his two sons being crushed by two enormous serpents). All these date from about 240 to 50 B.C.—for the culture did not immediately end with the Roman conquest.

The great frieze of the altar of the temple in Pergamum depicts a battle between gods and giants with tremendous realism and brutal violence far removed from the serene art of classical times. Portrait sculpture is typical of Hellenistic art, where it may almost be said to have been invented, since such ventures in the past had been idealistic rather than realistic.

The great Hellenistic cities were geometrically planned and fine public buildings made their appearance in which the slender and graceful Ionic of the ornate Corinthian columns took the place of the more austere and heavy classical ones. Alexandria was celebrated for its vast libraries and was the centre of a brilliant intellectual life (the Septuagint or Greek translation of the Bible was prepared here). Here too worked the mathematicians Euclid and Archimedes, the physicians Erasistratus and Herophilus, and the geographer Pytheas.

But Hellenistic literature was a pale reflection of the glories of the past and we mention only the comedies of Menander and the pastoral verse of Theocritus of Syracuse.

Hieratic Art, a type of art (typified by the major part of the art of ancient Egypt) which is (*a*) exclusively religious and (*b*) conventionally based on earlier forms and traditions.

History painting represents scenes from the Bible, mythology, ancient history or classical literature which have an elevated or moralising theme. The idea that history painting was the highest form of art was cultivated by the French Academy in the seventeenth century and the Royal Academy of England in the eighteenth.

Hudson River School, a loosely linked group of American artists, including Thomas Cole and F. E. Church, who practised in the middle of the nineteenth century. They painted mostly landscapes, concentrating on the more remote parts of the north-eastern United States, and they were influenced by the Sublime (*q.v.*) paintings of the English artists Turner (*q.v.*) and John Martin.

Their emphasis on a specifically American landscape, especially the Hudson River Valley which gave the group its name, had a distinctly nationalist flavour.

I

Icon, in Byzantine culture, a sacred image of Christ or saints. The reverence for such images was often connected to idolatry and led to the Iconoclastic Controversy of the eighth century. Icons are common in Greek and Russian orthodox churches, and the image itself was interpreted as an intercessor between the worshipper and the holy person depicted.

Iconography, the study of signs and symbols in art, or the interpretation of subject-matter. This practice often involves a strict set of rules, and it requires a detailed knowledge of diverse religious, literary and classical sources.

Illuminated MSS. of great value and beauty of decoration exist in most public museums and in many private collections, some of them being of great antiquity, especially those of ancient Egypt executed on papyri. Greek and Latin specimens are also numerous, and the British Museum contains fine examples of all these kinds and also an extensive collection of medieval English MSS.

The 1,300-year-old Lindisfarne Gospels are believed to have been written and painted by just one person, Bishop Eadfrith of Lindisfarne, working around 715–720 in honour of St Cuthbert.

Impasto, oil or acrylic paint applied thickly to the surface of the canvas so that the brush strokes themselves are noticeable. This technique was commonly used by artists from the nineteenth century such as Vincent van Gogh as a means of emphasising the paint surface and thus drawing attention away from the illusionistic qualities of painting.

Impressionism, the most important and influential movement in 19th cent. European painting. It gained its name, at first contemptuously, in 1874 from a picture painted by Claude Monet and named by the artist *Impression: soleil levant* ("Impression: sunrise"), which showed the play of light on water with the observer looking straight into the rising sun. Although intended to be the ultimate form of naturalism the inspiration of the school had been the scientific study of light with an attempt to render the play of light on the surface of objects.

Feeling that putting a line around a form was bound to cause it to look unnatural, the Impressionists used bright colours corresponding to the spectrum and unmixed on the palette, and noted that an object of any given colour casts a shadow tinged with the complementary one (*e.g.*, red-green, yellow-blue). Hence bright sunlight was represented in clear yellows and orange with violet shadows. The first Impressionist exhibition held in Paris in 1874 aroused derision with its paintings by Monet, Renoir, Sisley, Pissaro, Cézanne and Degas among others. Impressionism subsequently led to the entirely artistic and anti-naturalist movement of Post-impressionism. Cézanne, who felt that he wanted to produce "something solid and durable, like the art of the museums" was only dubiously impressionist, as were also Degas and Renoir. Of course, in the wider sense of the word (*i.e.*, the recording of an ephemeral impression of a scene), Whistler, Turner and even Rembrandt used the technique.

Intaglio, a term used to describe types of printing such as etching and engraving in which the design on the plate is incised. This is opposed to relief printing, such as woodcuts (*q.v.*), in which the raised portion creates the design.

International Gothic, a style of art that existed throughout Europe in the late fourteenth and early fifteenth centuries. The style was characterized by an aristocratic elegance and a combination of Gothic (*q.v.*) mannerism with a new interest in realistic depiction. The style was spread by itinerant artists, and is best typified by Gentile da Fabriano and Jacopo Bellini in Italy and the Limbourg brothers in France.

Intimisme refers to the scenes of domestic interiors painted by Edouard Vuillard and Pierre Bonnard in the late 19th and early 20th centuries.

Intonaco, the final layer of plaster onto which frescos are painted. It serves as a protective ground between the other layers of plaster and the paint itself.

J

Junk Art, or trash art, particularly referring to sculptures, was popular in the late 1950s, when artists began using rubbish and other rejected items of consumer culture to create works of art. Generally, Junk Art refers to assemblages *e.g.* those produced by Robert Rauschenberg (1925–2008), a pivotal figure in a great age of American painting.

K

Kinetic Art denotes works of art which actually move or give the illusion of so doing. An early exponent of kinetic art was the American sculptor Alexander Calder (1898–1976) when he launched his famous "mobiles" in the early 1950s. Since then, constructions which rotate, jump, blink with lights, *etc.* have been made by many artists and the genre is being further elaborated upon today. Kinetic painters give a visual illusion of movement to their pictures by the use of particular colour contrasts or by a skilful play with spirals, squares, *etc.* in black and white, sometimes with colours blended in.

Kit-Cat in the early eighteenth century was a name given to a club of Whigs who met in a tavern overseen by Christopher Catling. In artistic terms, the name refers to a series of portraits painted by Godfrey Kneller (*q.v.*) which represented the Kit-Cat Club members. Kneller's innovatory works were larger than half-length portraits but smaller than whole-lengths, and through the inclusion of at least one-hand, they allowed a greater variety of posing than previous small portraits. Kit-Cat later came to refer to a portrait of this size (136″ × 28″). Kit-Kat chocolate bars are thought to have taken their name from the club.

Kitchen Sink School was a group of artists, including John Bratby, who produced Social Realist (*q.v.*) paintings after the Second World War. The name "kitchen sink" referred originally to the concerns of the "Angry Young Man" movement initiated by the playwright John Osborne in 1956. This cultural tendency embraced a strong working-class consciousness as well as post-war disillusionment.

Kitsch (German "vulgar trash") describes art defined from an elitist perspective as being of inferior, even degenerate taste, a vulgar, sentimental, inferior copy of an existing style. In the 1930s Kitsch was theorised by Theodor Adorno as an outcome of what he calls the "culture industry" and by Clement Greenberg as the product of a bourgeois world dominated by money and desire, targeting an audience incapable of genuine aesthetic enjoyment due to their lack of education and interested only in consumption. For Milan Kundera, Kitsch was one of the instruments through which totalitarian systems controlled the masses and levelled their cultural standard by imposing a sanitised view of the world in which all answers are given. The term was at least partly rehabilitated by Pop art (*q.v.*) and further by Postmodernism, whose ironic, pastichising outlook is predicated on the blurring of the boundaries between "high" and "low" art.

In the United States, the term "schlock" (from Yiddish "cheap", "defective goods") is sometimes used as equivalent to Kitsch.

L

Land Art *See* **Earthwork.**

Lay figure, a jointed doll or dummy used by portrait painters especially in the eighteenth century. Lay figures could be manipulated to provide a diversity of poses, and they could be dressed to allow a more detailed study of costume. Their use reflected the general artificiality of portrait painting in eighteenth-century England and the need for short cuts to produce speedy results.

Linocut, a woodcut (*q.v.*) in which the plate is made from linoleum rather than wood. The soft flexibility of the linoleum allows for an easier process of cutting and larger, bolder effects. It was invented by the artists of Die Brücke (*q.v.*) and used by Kandinsky.

Lithography, the art of drawing on stone and printing therefrom, was discovered by Alois Senefelder about 1796, and was introduced into England a few years later. Many improvements in the art have been made, especially in chrome-lithography and photo-lithography.

Luminism is not a movement as such, but a name given to works produced by American landscape painters that capitalised on the importance of light effects in the nineteenth century. Artists such as George Caleb Bingham and the painters of the Hudson River School (*q.v.*) produced panoramic views dominated by sky. Luminism is also characterised by smooth canvases in which no obvious brush strokes or paint surface could be detected. These qualities distinguished it from the visible brush strokes of the impressionists (*q.v.*).

M

Macchiaioli, I, a group of Italian artists working mainly in Florence between 1855 and 1865. The name refers to the *macchia* or patches of colour that they used in their paintings. They were influenced by the Barbizon School (*q.v.*), and their technique in many ways prefigured that of the Impressionists (*q.v.*).

Magic Realism refers generally to a type of painting which combines a realistic technique with fanciful or dream-like subject matter, as in the paintings of René Magritte and other Surrealists (*q.v.*). In its strictest sense, Magic Realism was a type of German realist art produced in the 1920s; it is contrasted with Verism (*q.v.*), and both are considered aspects of *Neue Sachlichkeit* (*q.v.*). The term was coined by the German critic Franz Roh.

Mannerism, a sixteenth-century art movement, chronologically positioned between the High Renaissance (*q.v.*) and the later Baroque (*q.v.*). Unlike these movements, the characteristics of Mannerism are less defined. Generally, Mannerist paintings are distinguished by their sophistication, artificiality and anatomical distortion. They include unusual or brash colours and sometimes their treatment of subject-matter is disturbing. Parmigianino and Giulio Romano (*q.v.*) produced works considered Mannerist, but the term is also applied to artists such as Tintoretto (*q.v.*) and El Greco. It has been used equally to refer to sixteenth-century architecture in which playful satires on classical forms are apparent.

Maquette, a clay or wax model for sculpture.

Marxist art history was a development in art-historical scholarship which sought to align art with the economic and political conditions behind its production. Although Marx himself did not tackle the subject of aesthetics, art historians have applied Marx's ideas of class struggle and bourgeois/proletarian conflict to pictures. With the collapse of communism following the fall of the Soviet Union the term is no longer in common usage.

Medium, strictly speaking, is the liquid, whether oil or egg yolk, used with colour pigments to make paint. In a more general sense, it refers to painting, sculpture, charcoal drawing or any other method used by an artist.

Metaphysical Painting (**Pittura Metafisica**), a name given to the work of Giorgio de Chirico (*q.v.*) and Carlo Carrà. These two artists met in a military hospital in Ferrara in 1917, where they gave this name to paintings which avoided the mechanical nature of modernist movements such as Cubism (*q.v.*) in favour of a dream-like evocation of more spiritual concerns. Their works contained unusual combinations of images which were painted in a realistic style, and they employed methods such as perspective (*q.v.*) drawn from Italian Renaissance painting. The dream imagery of de Chirico was very influential on the Surrealists (*q.v.*), particularly those who practised Magic Realism (*q.v.*).

Mezzotint, a technical method for producing graphic work and works of art. A copper plate is made rough by close cross-hatching, so that a print from it produces an even black. When parts of the cross-hatching are scraped away, these areas will come out white when printed. By skilful use of his tools, the artist or technician can produce pictures finely graded from black to white and with a velvety black as background. The principles of the method were known and practised, for instance, by Rembrandt, but mezzotint became most popular for the reproduction of famous paintings from the end of the 18th cent.

Miniature, a small painting, usually a portrait. The term originally referred to medieval manuscript illumination (*q.v.*), but by the sixteenth century, it was used to signify small pictures painted on card. Miniatures became especially popular for keepsake portraits in the eighteenth century, and they often parroted the currently fashionable styles of oil painting.

Minimal Art was a movement which began in the United States in the 1960s. As its name implies it involves art, usually sculpture, which is reduced to its most essential form. Examples tend to be assemblages (*q.v.*) composed largely of limited abstract shapes. It has been seen as a reaction against Expressionism.

Mobile, a type of sculpture popularised by Alexander Calder in the 1930s. Mobiles are composed of flat geometric shapes hung on string and wire and allowed to move, or are moved by mechanical means. If mechanical means are used, mobiles can be considered Kinetic Art (*q.v.*).

Modello, a small preliminary painting used as a "try out" for a larger painting. Unlike sketches, which are often unfinished or merely summary, modelli prefigure the final painting in great detail. In the Renaissance (*see* **Section J**) they were used as a sort of advertisement by artists trying to convince patrons of the worth of their work.

Monotype, as the name suggests, refers to a printing process whereby only one impression can be made from each prepared plate. Monotypes are created by painting in oils directly onto a copper plate and then pressing the plate onto a piece of paper. This process was popular with twentieth-century artists such as Chagall (*q.v.*).

Montage, like collage (*q.v.*) involves the arrangement of diverse images together on a sheet of paper. But montage refers specifically to components which are complete in themselves (*see* **photomontage**), rather than abstract forms.

Mosaic, art of arranging small pieces of coloured glass, marble, or other materials in such a fashion as to produce a decorative pattern. Some of the best examples of Byzantine mosaics are to be seen at Ravenna, Rome, Venice and Sicily.

N

Nabis, the (the "Prophets"), the group of French painters who followed the Symbolist (*q.v.*) concerns of Gauguin. Between 1889 and 1899, Pierre Bonnard (*q.v.*), Edouard Vuillard and Maurice Denis explored the symbolic possibilities of colour first examined by Gauguin in 1888. They were particularly interested in the use of large patches of colour to convey spiritual intensity. *See* **Cloisonnism**.

Naive Art results from either a real or seeming lack of technical skill. This produces child-like images which offer a very literal form of Realism (*q.v.*). Paradoxically, naive art became popular in the late nineteenth and twentieth centuries, with the work of artists such as Le Douanier Rousseau (*q.v.*). A revival of interest in the simple expression of children's art which characterised modern movements such as German Expressionism (*q.v.*) may be partly responsible for this.

Narrative Art, a type of art popular during the late 19th cent. based on the principle: "every picture tells a story". The term, although often applied derisively, suitably describes many works of considerable artistic merit: *e.g.*, Hogarth's *Marriage à la Mode*, the Bayeux Tapestry, *etc.*

Naturalism in painting has been defined as "a direct and spontaneous approach to nature"—to landscape primarily. Constable, Turner and Boudin were among the great naturalist painters of the 19th cent.

Nazarenes, a group of German Romantic artists who worked in Rome in the early nineteenth century. In 1809 Friedrich Overbeck and Franz Pforr formed an artistic organisation called the Brotherhood of St. Luke in Vienna. They carried their interest in the revival of religious art to Rome in 1810, where they moved into an abandoned monastery and were joined by other artists. They hoped to capture the spirit of the Middle Ages through historical and religious subjects, and they were instrumental in the revival of fresco (*q.v.*) technique.

Their large-scale murals and historical scenes for the German ruling class led them to be associated with the intensification of German nationalism in the nineteenth century.

Neo-Classical Style, term applied to the revival of classical logic and order after the extravagances of Rococo (*q.v.*), beginning in France in the mid-18th cent. and finding expression in architecture and the decorative arts. The style retains some of the daintiness of Rococo, furniture is on a small scale, often gilt, and silks and porcelain favour pastel shades. Straight lines take the place of the wild curvatures of Rococo and classical details like festoons and urn forms are used in many contexts and materials. Its English version is closely associated with the name of the architect Robert Adam whose light and graceful adaptations of Greek and Roman forms were introduced into English country houses. In France the style is sometimes called *Style Louis XVI*. Eventually the Neo-Classical style merges into Empire (*q.v.*).

Neo-Expressionism, or Bad Art, refers to an international art movement of the late 1970s and 1980s involving the revival of Expressionist (*q.v.*) concerns. The prominent artists include George Baselitz and Francesco Clemente.

Neo-Impressionism, a development of Impressionism (*q.v.*) by Seurat and Signac during the 1880s who devised the method of painting known as *pointillism* (the application of pure colours in minute touches or spots to form a composite whole, based on a knowledge of the laws of colour and optics). One of the best-known examples of this technique is Seurat's *Sunday Afternoon on the Grand Jatte*.

Neo-Plasticism was a name used by Mondrian for a type of art which avoids representation in favour of abstraction. Mondrian's principles resulted in canvases which consisted solely of primary colours, black and white, and horizontal and vertical lines. His intention was to create an art which could have meaning for everyone, but paradoxically, his works usually puzzle the uninitiated. Neo-Plasticism was promoted by the journal, *De Stijl* (*q.v.*).

Neo-Romanticism is a British art movement which began before the Second World War. Artists such as John Piper and Graham Sutherland (*q.v.*) initiated a revival of interest in the Romantic landscape painting of William Blake (*q.v.*) and Samuel Palmer (*q.v.*). This concern for evocative native landscapes was a manifestation of pre-war nationalism.

Neue Sachlichkeit, Die (The New Objectivity), a name given by the art dealer G. F. Hartlaub to describe a diverse group of German artists who rejected abstraction during the 1920s. These artists all attempted to represent reality, either through a precise, detailed Magic Realism (*q.v.*) or a satirical and scathing Verism (*q.v.*). The first *Neue Sachlichkeit* exhibition was in 1923. The movement ended with the rise of the Nazis in the 1930s.

New English Art Club, an organisation formed in 1886 in reaction against the stale practices and politics of the Royal Academy. The members of this group, including Walter Sickert (*q.v.*) and Philip Wilson Steer (*q.v.*) were trained in France, and they preferred the informal *atelier* (*q.v.*) system of education to the rigid strictures of the Royal Academy Schools. Their work was influenced by Whistler (*q.v.*) and Jules Bastien-Lepage.

Newlyn School, the name given to a group of artists who congregated in Newlyn, Cornwall during the 1880s and 1890s. The group included Laura Knight and Stanhope Forbes, and they were particularly concerned with *plein air* (*q.v.*) painting.

Non-Objective Art is the correct name for what is usually called Abstract Art (*q.v.*). Its name suggests that the representational object has been obliterated, whereas "abstract" implies that the work of art is a simplification or modification of some real object.

Novecento Italiano, an Italian art movement of the 1920s which encouraged a return to the principles of Italian Renaissance (*see* **Section J**) art. The interest in the Italian past was more than simply a stylistic phenomenon, as it was strongly connected with the nationalist spirit of Fascism. The artists of the group included Mario Sironi and Achille Funi, and they held their first exhibition in the Pesaro Gallery, Milan, in 1922.

Novembergruppe, a group of left-wing Berlin artists formed in 1918. The members, including Max Pechstein, were committed to socialist principles and wanted an art capable of appealing to the masses. The name of the group came from the November Communist uprising in Berlin of 1918.

O

Objet trouvé. *See* **Found object.**

Omega Workshops, a cooperative founded by Roger Fry (*q.v.*) in 1913 aimed at producing quality decorative art. The artists of the Bloomsbury Group (*q.v.*), such as Duncan Grant and Vanessa Bell, were involved, and they decorated furniture for a small number of patrons. The impracticalities of their enterprise led to the organisation's demise in 1920, after sales had declined during World War I.

Op Art, an art based solely on perceptual or optical effects, which was particularly popular in the 1960s. Its practitioners included Bridget Riley.

Orphism (Orphic Cubism). In response to the monochromatic coldness of Cubism (*q.v.*), the artists Robert and Sonia Delaunay began producing paintings in which colour was fragmented in the same way that the Cubists broke up form. This prismatic treatment of colour was called Orphism by the poet Apollinaire in 1912. Orphism differs further from Cubism in its emphasis on movement and city life, qualities more obviously characteristic of Futurism. Orphist paintings eventually became totally abstract, but the movement did not last beyond the First World War.

P

Panorama, a circular painting placed inside a large cylinder, in which people can sit or stand. Panoramas could be walked around, or they were moved mechanically to create a sense of total environment. They were invented in Scotland by Robert Barker, who painted panoramic views of Edinburgh in the late eighteenth century, and they quickly became a popular form of entertainment. Their subjects included exotic scenes and Picturesque (*q.v.*) landscapes, but they also depicted recent military campaigns during the Napoleonic wars. This latter quality gave panoramas the value of reportage and enhanced their accessibility to a wider public.

Papier collé. French for "pasted paper", a type of collage (*q.v.*) popularised by Braque from 1913. This involved gluing bits of wallpaper or newspaper to a canvas. This process became a major aspect of Synthetic Cubism (*q.v.*), and it was used by Matisse (*q.v.*) for his paper cutouts.

Pastel, a chalk composed of powdered pigments which produces delicate but fragile images. The soft quality of pastel became especially popular in eighteenth-century European portraits.

Pentimento, bits of painting which become visible when the top layer of paint wears away. Often pentimenti signal an artist's earlier rejected experiments, and they are therefore used both as authentication and as a means of studying the processes of work stages of an artist.

Performance Art is a general term referring to a quasi-theatrical event which is considered art. The agitational demonstrations of the Futurists (*q.v.*), the nonsense recitations of the Dadaists (*q.v.*) and the Happenings (*q.v.*) of the 1960s are all examples of this type of art.

Perspective, a space-creating device used most frequently by Italian Renaissance (*see* **Section J**) artists. Linear or one-point perspective involves mathematically calculating a vanishing point where a series of parallel lines converge. In Renaissance painting, these lines are often created by floor patterns or carefully placed bodies, which lead the eye back into the picture to give a sense of depth. The creation of three-dimensional effects on a two-dimensional surface was particularly important for the Renaissance idea of optical illusionism, although the effect produced by perspective is only approximate to true visual experience. One-point perspective was used less frequently after the fifteenth century, but aerial perspective (*q.v.*) was commonly employed for several centuries afterwards.

Photomontage, a type of montage (*q.v.*) consisting wholly or partly of photographs. This technique was common among the Berlin Dada artists (*q.v.*), who used photographs from fashion magazines and other forms of popular culture to make satirical attacks on the superficiality of Weimar society.

Picturesque, with a capital "p", is an aesthetic term related to the "sublime" (*q.v.*) coined by William Gilpin in the eighteenth century to describe landscapes which looked "like a picture". Like the Sublime, the Picturesque was said to instill emotions in the observer, who associated the sight of rough beauty, ruins or irregular landscapes with various sentimental or melancholy moods. In the 1790s the term became the focus of a heated aesthetic debate which included such participants as Richard Payne Knight and Uvedale Price. The growing popularity of Picturesque ideas inspired artists and amateurs to take Picturesque tours, as in the Lake District and Wales, in order to discover the possibilities in rugged or unusual landscapes.

Pietà (Italian for "pity"), a devotional image of the Virgin Mary with the dead Christ on her lap. Michelangelo's Pietà, now in St. Peter's, Rome, is the most famous example.

Plein air (French for "open air"), refers to painting out of doors. Before the nineteenth century, landscape painters commonly produced their works in a studio from sketches or studies. The French Barbizon (*q.v.*) painters cultivated the opposing practice of painting outside—a method that was wholeheartedly adopted by the Impressionists (*q.v.*).

Polyptych, an altarpiece (*q.v.*) with more than one panel, such as a diptych (*q.v.*) or triptych (*q.v.*).

Pop Art, a phenomenon of the 1960s and 1970s which involved transforming objects of popular culture into works of art. The movement started in Britain, when a group of artists at the Institute of Contemporary Arts began using images from comic books and advertising in their art. Pop art either attacks modern consumer culture or it glorifies it nostalgically. Its main practitioners were Peter Blake and Richard Hamilton in England and Andy Warhol and Roy Lichtenstein in America. Lichtenstein's Whaam! and Crying Girl paintings defined the 1960s movement. Their female counterparts included Pauline Boty, Rosalyn Drexler and Marisol.

Portland Vase, one of the most renowned specimens of ancient art, long in the possession of the Portland family. In 1810 it was loaned to the British Museum. Here it was shattered in 1845 by a stone from a maniac's hand, but has been skilfully restored. It is said to have been found in the 17th cent. in an ancient tomb near Rome. It was purchased from the Barberini family in 1770 by Sir Wm. Hamilton, subsequently sold to the Duchess of Portland. The vase, which is actually a two-handled urn, stands about 25 cm high, is of transparent dark blue glass, ornamented with figures cut in relief in overlaid white opaque glass. It was purchased by the British Museum in 1945. *See* **Glass, Section L.**

Post-Impressionism, a term introduced by Roger Fry to describe the exhibition of paintings sponsored by himself in London (1910–11) officially entitled "Manet and the Post-Impressionists". The exhibition included paintings by Manet, Cézanne, Gauguin, Van Gogh, Seurat, Signac, works by Matisse, Rouault and the *Fauves* (*q.v.*), and sculpture by Maillol. In a second exhibition, held in 1912, Picasso and the Cubists were also represented.

The term therefore refers to the movement in modern art which reacted against the transient naturalism of the Impressionists by concerning itself primarily with colour, form and solidity. Most artists include Cézanne, Van Gogh and Gauguin as the main Post-Impressionists and maintain that it prepared the way for Fauvism, Cubism and Expressionism.

Post-Modernism is a cultural phenomenon. From the end of the Second World War, the failure of Modernism in all of its manifestations was evident, and artists, architects and writers began seeking other solutions to the problems of contemporary life. Post-Modernism is not one style but many styles, and it is often self-referential, playful or parodic. The exact meaning of the term which came into general use in the 1970s, and those works of art which fall within its parameters, are a subject of continual debate, but a number of post-war developments, such as Happenings (*q.v.*) could be seen to be in its sphere.

Post-Painterly Abstraction was a term invented by the critic Clement Greenberg in 1964 to refer to non-objective (*q.v.*) artists who were not members of the Abstract Expressionist (*q.v.*) movement. The paintings of Kenneth Noland, Frank Stella and others were considered to fall within this definition, as they painted canvases with large patches of colour and which were carefully planned, rather than spontaneous, as in Action Painting (*q.v.*).

Predella, the panel or panels running along the bottom of an Italian Renaissance (*see* **Section J**) painting, and usually containing a series of narrative scenes to complement the main devotional subject of the altarpiece itself.

Pre-Raphaelite Brotherhood was the name given to their school of thought by three British artists, Dante Gabriel Rossetti, J. E. Millais and W. Holman Hunt, who in 1848 revolted against the academic art of their time and advocated a return to the style of the Italian painters prior to Raphael—the simple naturalism of the Primitives, such as Botticelli, Fra Angelico and Filippo Lippi. Thus they avoided the use of heavy shadows and painted on a white ground in bright colours—a technique which aroused the ire of those used to the dark and murky canvases of the contemporary romantic artists. Although they held these principles in common the three members of the "P.R.B.", as it was popularly called, were really quite different in other respects. Thus Rossetti (who for some reason is always thought of as the typical Pre-Raphaelite) produced works of a highly romanticised mediaevalism which, apart from certain aspects of technique, bear not the slightest resemblance to the sentimental naturalism of Millais or the much more dramatic realism of Holman Hunt (*e.g.*, in *The Scapegoat*). The Brotherhood was later joined by a number of lesser artists, but its works are not commonly accepted with enthusiasm today when the general feeling is that they are sentimental and religiose rather than the product of deeply-felt emotions. Ruskin in his writings had defended their work but the movement ended in 1853.

Primitive Art. The word "primitive" has a number of different meanings: (1) the art of prehistoric communities (*e.g.*, the famous animal cave-drawings of the Aurignacians, *c.* 25,000 B.C., at Altamira in Spain); (2) the art of modern primitive communities (*e.g.*, Bushman rock-paintings); (3) child art; (4) peasant art which springs from a spontaneous desire to impart beauty to objects of daily use and shows a tendency towards abstraction. Peasant art has many features in common the world over, the woodcarving of the Norsemen being almost indistinguishable from that of the Maoris; (5) the modern school of primitive painting in which naïveté of presentation is either the aim of a highly sophisticated mind (*e.g.*, the self-taught French painter Le Douanier Rousseau (d. 1910), or arises naturally from a simple one (the American "grandma" Moses (d. 1961) who began to paint in her seventies). *See also* **Cave Paintings, N5.**

Provenance records the whole history of the ownership of a painting, from its first commission or sale to its present location. A confident provenance is often used to authenticate a work of art, but it can be equally revealing about patterns of taste and art purchase through the centuries.

Purism was a reaction against Cubism (*q.v.*) advocating machine-like clarity and observation which drew upon some of Cubism's methods. The term was coined in 1918 when Amédée Ozenfant's book *Après le Cubisme* rejected the "decorative" qualities of Cubist painting, which he felt did not respond properly to the needs of modern industrial society. Purist painters such as Charles-Edouard Jeanneret (Le Corbusier, *q.v.*) and Ferdinand Léger embraced this "machine aesthetic", but it was most influential on architecture.

Putto, a fat naked boy used as a decorative addition to painting and sculpture, especially in the Baroque (*q.v.*) period.

R

Rayonism was a short-lived Russian art movement including the work of Mikhail Larianov and Natalia Goncharova. The ideas behind it were consolidated in the 1913 Moscow Target exhibition. In the exhibition catalogue, Larianov described Rayonism as a combination of Cubism (*q.v.*), Futurism (*q.v.*) and Orphism (*q.v.*). It involved the use of intersecting rays of light, and partial or total abstraction.

Ready-made was a word used by the twentieth-century artist Marcel Duchamp to signify an object selected by an artist to be displayed as a work of art. The artist does not actually produce the work but merely presents it, thus changing the significance of an otherwise ordinary object. A ready-made is similar to a found object (*q.v.*), but it is less concerned with aesthetic values. The presentation of a ready-made in some ways undermines the whole process of production and display of art and should be considered as a somewhat cynical statement.

Realism is a vague term. As a movement in art it can be said to have started with Gustave Courbet in the mid-19th cent. in his revolt against the classicism of Ingres and the romanticism of Delacroix. He was a man of strong radical views, and like Zola, Balzac and Flaubert in literature, turned to the actuality of everyday life, recording it with frankness and vigour. Some young English painters, notably Bratby, of the "kitchen sink" school, practise what some describe as social realism. In another sense, realism is an attitude concerned with interpreting the essential nature of the subject, revealing truths hidden by the accidentals of ordinary visual appearance. Thus form becomes more significant than content. Beginning with Cézanne and Van Gogh this trend passes on to Cubist and Abstract painting. *See also* **Section J** (philosophy).

Regency Style is the English version of the French Empire (*q.v.*) and approximately covers the period of the regency of Prince George, later George IV, from 1811 to 1820. It is somewhat less austere than the French style, and contains elements of the fantastic and exotic absent from Empire. The most famous monument of Regency style is the Royal Pavilion at Brighton, built for the Prince Regent by John Nash. (Regency style should not be confused with the *Régence* style in France, fashionable during the regency period between the death of Louis XIV in 1715 and the ascent to the throne of Louis XV in 1723. Here the English equivalent is Queen Anne style.)

Relief in sculpture is of three kinds—high relief (*alto-relievo*), in which the figures stand out to the extent of one-half of their natural proportions, low-relief (*basso-relievo*) when the figures project but slightly; and middle-relief (*mezzo-relievo*), when the projection is intermediate.

Renaissance. *See* **Section J.**

Repoussoir is French for "to push back". It signifies an object, usually a tree, which borders the foreground of a picture and draws the eye deeper into the space of a painting. It is especially used in landscape paintings by artists such as Claude (*q.v.*), where it serves a primarily compositional purpose.

Rococo, an architectural style which was, in effect, the final stage of **Baroque** (*q.v.*). The name first came into use about 1830 to describe the period 1720–70 and means "shell-shaped" (French *Rocaille*), since the shell was a favourite motif in Rococo ornamentation. At about the beginning of the 18th cent. the heavy older type of Baroque began to show even less restraint than had characterised it in the past; it became still less utilitarian, and showed a kind of playful light-hearted vitality which manifested itself in a wealth of ornamental invention. Baroque was flamboyant and robust, Rococo dainty, graceful and smiling. Its ornaments are frequently asymmetrical, and in this Rococo is unique among the historical styles of Europe. In architecture Rococo is naturally found in those areas where the Baroque had flourished, *i.e.*, Munich, Prague, Vienna and Dresden. In painting, the best expressions of Rococo are to be seen in the works of the French painters Watteau (d. 1721), Boucher (d. 1770), and Fragonard (d. 1806).

Romanticism. *See* **Section J.**

S

Sacra conversazione, a type of altarpiece (*q.v.*) which originated in fifteenth-century Italy. It consists of the Madonna and Child with a group of saints standing around her. It departs from the Gothic (*q.v.*) tradition of separating the Madonna from saints in polyptychs (*q.v.*), and it also allows a greater apparent ease of association among holy figures.

St. Ives painters, a group of artists who congregated in St. Ives, Cornwall, in 1939. The group included Adrian Stokes, Barbara Hepworth and Ben Nicholson (*q.v.*). Unlike other such artistic colonies, this group was diverse in both style and subject-matter, though it tended to favour avant-garde work.

Salon, a French royally-sanctioned art institution. In 1667 the first salon was the exhibition of works by artists of the Académie Royale, shown in the Salon d'Apollon of the Louvre. There academic artists exhibited occasionally until 1737, when exhibitions became a biennial event. Art exhibitions were consolidated into the academic structure in the eighteenth century through the introduction of juries, who rejected paintings they did not feel appropriate for the Salon. After the French Revolution, the Salon was held every year and became increasingly important in the French art world until the 1860s, when it was challenged by alternative salons (*see* **Salon des Refusés, Salon d'Automne** and **Salon des Indépendants**).

Salon d'Automne, one of the salons formed in competition to the official academy Salon (*q.v.*). It began holding exhibitions from 1903, the most famous of which was the 1905 exhibition. This included works by Matisse, Dérain and Vlaminck which started the "Fauvist" movement.

Salon des Indépendants, one of the salons formed in competition to the official academy Salon (*q.v.*). It began in 1884 on the initiative of the *Société des Artistes Indépendants*, which included among its membership Seurat and Signac. This Salon rejected the jury system of the official Salon and became a major showplace for Post-Impressionist (*q.v.*) painting.

Salon des Refusés, an alternative salon set up in 1863 to house all the paintings rejected by the official Salon (*q.v.*). It resulted from an intensification of the anger and discouragement of French artists whose works had been consistently rejected by the Salon. To appease them, Napoleon III allowed all rejected works to be exhibited separately. The exhibition induced much derision and distaste in a conservative public, but it became the starting point for a more considered reaction against the French Academy and the hegemony of the official Salon. Manet's (*q.v.*) *Déjeuner sur l'herbe* was one of the works shown here.

Scumbling, when an opaque colour is applied over an already existing colour but allows the other colour to show through. Scumbling creates a textured or broken effect on the canvas surface.

Secession (**Sezession**), the name given to a series of rebellions against the academic system in Germany and Austria during the 1890s. Throughout Europe at this time, the limitations of academies were becoming apparent to artists who wanted to experiment with new methods, ideas and techniques. The Munich Secession was the first to express this sense of rebellion by turning away from academic classicism towards an art nouveau (*q.v.*) style. Closely following this were the Vienna Secession (beginning 1897), which was also sympathetic to art nouveau, and the Berlin Secession (from 1899) which encouraged an Impressionist (*q.v.*) style.

Secco, Italian for "dry", a term applied to fresco painting. Usually in a fresco, the plaster is painted while wet, but the *secco* method involves waiting for the plaster to dry before painting it. In the Middle Ages and the Renaissance (*see* **Section J**), this technique was usually used for touching up a finished fresco. If it was used exclusively, it caused more rapid deterioration in the painting.

Serial Art, a term used mainly in the United States to identify two forms of avant-garde which have in common a mathematical structuring principle. One refers to works conceived as part of a series or a larger group in which the meaning of individual parts is related to the meaning of the whole on a repetitive basis. The intention is to free the work of art from the tyranny of traditional concepts such as originality and uniqueness. The other, more specific understanding of the term is related to a type of minimal art in which simple, uniform, mass-produced component parts are put together in a regular pattern. Artists who have produced serial art include Tony Smith and Carl Andre.

Seriography. *See* **Silk screen printing**. (*below*).

Shunga The erotic art of Japan. It flourished first in painted scrolls.

Sfumato, Italian for "smoke", is a term used in the sixteenth century to signify gradations of colour and tone which avoided stark outlines and created a sense of depth. It was applied especially to the soft tonal effects of Leonardo da Vinci's (*q.v.*) paintings.

Silk screen printing is also called seriography. It is a Japanese technique imported into Europe in the nineteenth century, which involves masking a silk screen with pieces of paper or cardboard and then pressing colour through the screen onto a piece of paper beneath it. Although a skilled designer is necessary for a successful silk screen print, the actual process of making the print can be carried out by anyone.

Sinopia, an earthy red-brown colour used to make a preliminary drawing for a fresco in the Middle Ages and also the Renaissance. The sinopia was applied first, then covered by intonaco (*q.v.*), which was then painted. It served as a preparatory sketch over which the final painting could be constructed.

Sistine Chapel. *See* **Section L**.

Social Realism, a type of Realism (*q.v.*) concerned not just with style but with subject-matter. The term is applied to paintings of the nineteenth and twentieth centuries which have social or political subtexts, especially of a Leftist variety. Social Realism possibly began with Courbet, whose unapologetic, even heroic, paintings of peasants were especially subversive during a period of political unrest in Europe (*c.* 1848–9). The term has also been used to describe the work of the American Ashcan School (*q.v.*) and the British Kitchen Sink School (*q.v.*).

Socialist Realism, as opposed to Social Realism (*q.v.*), had a very specific propagandist purpose. In its strictest sense, it signified the official art of the Communist USSR developed under Stalin's dictatorship. Its structures were laid down by the 1934 Soviet Congress. It used a Realist (*q.v.*) style with proletariat subject-matter as a form of instruction to the people. From 1934 until *glasnost*, it was the only official art of the Soviet Union.

Stijl, De (Dutch, "The Style"), a Dutch art magazine which perpetuated the Neo-Plasticism (*q.v.*) of Piet Mondrian and Theo van Doesburg. The magazine began in 1917, and its articles stressed pure abstract or non-objective (*q.v.*) form in painting, sculpture and architecture. Its subsequent influence was primarily in the realm of architecture, and the ideas of *De Stijl* were particularly influential in reforming the Bauhaus (*q.v.*) when Doesburg visited it in 1923.

Still-life, a type of painting which precludes the depiction of human beings and concentrates on everyday objects such as fruit or flowers. It was popularised in Holland during the seventeenth century, when its immediate appeal was appreciated by the art-buying middle-class, and it continued to be popular throughout the eighteenth and nineteenth centuries, when its most notable practitioners were Chardin (*q.v.*) and Cézanne (*q.v.*). Still-lifes (the accepted plural form) often took on emblematic or moralistic meanings, reflecting the vanity or transience of human existence, but despite their potential depth of meaning, they were considered the lowest category of painting by European art academies (*q.v.*).

This relegation of still-lifes also accentuated the repression of women artists, as they were excluded from official training institutions and often painted solely still-lifes.

Sublime, a term which has an ancient origin but was brought into the realm of aesthetics during the eighteenth century. Edmund Burke's (*q.v.*) *Enquiry Into the Origins of Our Idea of the Sublime and the Beautiful* (1757) postulated an aesthetic category which engaged the emotions. The sublime involved a feeling of awe or terror inspired by overwhelming natural forces. Burke's writings were influential on the growth of Gothic novels, and they were later used to good effect in landscape painting by artists such as Turner (*q.v.*) and John Martin.

Subway Art. *See* **Graffiti Art**.

Superrealism (**Hyperrealism, Photorealism**) describes paintings of the 1970s onwards which attempted to evoke a photographic illusion of reality. In some cases, the artist actually copies a photograph.

Suprematism, a term invented by the Russian artist Kasimir Malevich to describe his non-objective (*q.v.*) paintings, such as *White on White*. The theory behind Suprematism is complicated and involves an attempt to articulate in visual terms a "fourth dimension". Malevich's first exercises in Suprematism occurred in 1913, and he officially christened the movement in 1915.

Surrealism. The aim of the Surrealist school of painting and sculpture is to overcome the barriers between conscious and unconscious mind, the real and unreal worlds of waking and dreaming. As such it has a long and respectable ancestry, although the term was not in use until 1922 when it was picked by André Breton from Guillaume Apollinaire who had used it in connection with certain works by Chagall.

However, Bosch in the 15th cent., Fuseli and Goya in the 18th, and many other purveyors of the weird and fantastic were the forerunners of modern Surrealism. The modern movement has broadly speaking taken two different directions: the first was towards complete fantasy and absurdity which took the form of "found objects"—*e.g.* a bird-cage filled with sugarcubes and a thermometer, a bottle-dryer, a bicycle wheel, or abstract works with strange and apparently irrelevant titles such as Paul Klee's *Twittering Machine*; the second towards highly detailed and realistic paintings of objects placed in strange juxtapositions—*e.g.*, Salvador Dali's trees with limp watches drooping over their branches.

Symbolism began as a literary term referring to French poetry of the 1850s, but in the 1880s and 1890s it was applied to painting. Symbolist artists rejected the tenets of Impressionism (*q.v.*), which they saw as too involved with perceptual response. Instead they concentrated on the representation of spiritual and subjective feelings, which often manifested themselves in religious or erotic subject-matter. Its French exponents included Puvis de Chavannes, Odilon Redon and Gustav Moreau, but the ideas of Symbolism soon spread throughout Europe.

Synchromism, an abstract movement founded in 1912 by two American artists living in Paris, Stanton MacDonald-Wright and Morgan Russell. Synchromism aims to unite music and painting by orchestrating colours like notes in the process of composing a symphony. The results are usually abstract dynamic shapes with a central vortex that explodes in complex colour harmonies.

Synthetism refers to the work of Gauguin's followers who, in the 1890s, produced paintings which included large patches of concentrated colour surrounded by black lines, as in Gauguin's *cloisonnism*. The root word "synthesis" refers to Gauguin's idea that painting should represent a concentrated synthesis of the artist's emotions.

Synthetist artists painted from memory, rather than copied the world before them as the Impressionists (*q.v.*) had done.

T

Tachisme is sometimes used synonymously with Abstract Expressionism (*q.v.*), but it strictly refers to a French movement of the 1950s which consisted of paintings composed of large blobs or *taches* of colour. It derives its name from the French for stain or splash.

Tapestry, a fabric largely used in earlier ages for wall decoration and hangings. It was known to the ancient Greeks, but in its modern form came into prominence in the 15th and 16th cent., when it was manufactured in a marked degree of excellence by the weavers of Flanders, especially those of Arras. The manufacture was introduced into England early in the 17th cent.

Nowadays the term is applied to worsted cloths for furniture coverings, and there are also various kinds of tapestry carpets now made. The most famous tapestries of old times were the Aubusson Tapestry and the Savonnerie. The Gobelin Tapestry factory, originated in Paris in the reign of Francis I, is still a national establishment. *See also* **Bayeux Tapestry, Section L.**

Tempera, a painting technique used commonly by medieval artists before it was superseded by oil painting in the fifteenth century. It is made by mixing powdered colour with egg yolk, egg white or the whole egg to create an opaque paint.

Tonalism, a term coined by the painter Samuel Isham (1855–1914) in his book *The History of American Painting* (1905) to refer to a trend in American painting in which idealised, intimate romanticised landscapes predominate and resemble Impressionism and Pictorial photography, popular at the same time.

Tonalism was practised by painters such as George Innes and Dwyght Tryon and by James Abbott McNeill Whistler, even though he did not technically belong to the American trend as he was mostly based in Europe.

Tondo, Italian for "round", is a circular painting or sculpture, popular in fifteenth-century Italy.

Triptych, an altarpiece composed of three panels hinged together. This is one of the most common types of altarpieces, as the two outer panels can fold together over the inner panel. The outer panels were thus usually painted on the inside and the outside to allow two different visual effects.

Trompe l'oeil literally means to "fool the eye". It refers to a considered attempt at illusionism that makes it difficult to tell whether or not a painted surface is real. *Trompe l'oeil* devices were commonly used in ceiling painting, and they were employed by the Cubists (*q.v.*) to create an amusing dissonance between optical space and the perspective distortions of Cubist space.

V

Varnish is a transparent hard, protective film, usually painted or sprayed over a finished painting in order to preserve it. Although varnish will help the paint to remain stable, it often darkens over time and paradoxically can cause extreme damage to a painting's surface.

Verism was a name given to the German *Neue Sachlichkeit* (*q.v.*) artists such as George Grosz and Otto Dix, who produced scathing, and often disturbing, satires on Weimar society in the 1920s.

Vienna School of Fantastic Realism. Founded by Ernst Fuchs (1930–2015), it emphasised clarity and detail.

Vorticism, a term coined by Ezra Pound to name a British art movement which began in 1913 on the initiative of Wyndham Lewis, Ezra Pound (*q.v.*) and Edward Wadsworth. The movement brought both Cubism (*q.v.*) and Futurism (*q.v.*) into England, as its practitioners were concerned with modern life as well as with the abrogation of the stale stability of established art. From 1914 the artists produced a magazine called *BLAST*, and they held their only exhibition in 1915. The First World War dissipated their momentum.

W

Wanderers, The, a group of nineteenth-century Russian artists who attempted to carry their ideas to the country peasantry. Reacting against the elitism of the Imperial Academy of Arts in St. Petersburg, artists such as Ilya Repin established itinerant exhibitions to show their Social Realist (*q.v.*) paintings of Russian peasant life and Russian history. Founded in 1870, the Wanderers continued to exist until the early twentieth century.

Watercolour, a technique of painting involving water soluble colours. Watercolour creates a transparent effect, as opposed to the opaque effect of gouache, (*q.v.*), which is particularly useful for landscape painting. It was used by Dürer (*q.v.*) in the early sixteenth century for landscape sketches, but it only became popular at the end of the eighteenth century with the growth of Picturesque (*q.v.*) tourism. The ease of using watercolour made it a particularly appropriate technique for amateurs.

Weaving. The interlacing of two or more threads at right angles to form a fabric is a craft that has been practised since ancient times. The main principle of the weaving loom is the same today as it was thousands of years ago; a warp extends lengthwise through the loom, the threads being held in separate regular order by being passed through a reed or "slay", while the weft is crossed through alternating threads of the warp by means of a shuttle which holds the weft. Thus the fabric is built up. Weaving was done by hand up to the early part of the 19th cent., when Cartwright's steam-power loom was introduced. The Jacquard loom for weaving figured designs dates from 1801.

Woodcut, a print technique which involves cutting into a block of wood, inking the block and then pressing it onto a piece of paper. The raised portions of the wood create the design, and the cut portions read as white spaces on the final print. It is one of the oldest printing techniques, and it was used from the fifteenth century. It was superseded by the more efficient method of engraving (*q.v.*), but it was revived in the early twentieth century by the German Expressionists.

World of Art (**Mir Iskusstva**), influential Russian art magazine and art movement which began in St. Petersburg in 1899. It was directed against the seeming parochialism of Russian art.

PART II. AN INTRODUCTION TO ARCHITECTURE

This basic introduction to British architecture deals with the chronological development of building styles and types from classical times to the present day. Leading architects are discussed with reference to their outstanding surviving creations. Although the study focuses deliberately on Britain, the important influences from overseas are discussed as are the classical Greek and Roman models on which much of the country's building was indirectly or directly based. A glossary of some terms is also included.

GREEK ARCHITECTURE

Although the Greeks never settled in Britain, their buildings are important here not so much in themselves but as a source and inspiration for later architects. The Greeks were responsible for devising the three basic orders in classical architecture: Doric, Ionic and most latterly Corinthian.

These orders with their particular base, shaft, capital and entablatures formed the basic vocabulary of Greek and Roman building and in their turn lay at the basis of Western European architecture from the Renaissance until the dawn of the Modern movement. The Greeks also made important discoveries about proportion and tricks of perspective, giving their columns and beams a slight curve (entasis, *q.v*) to make them appear straight when viewed from a distance. These fundamental rules together with the Greek building system represent the very basic sources of architecture.

The Greek Temple.

The typical Greek temple structure consists of an outer row of Doric columns arranged in a rectangular plan. These surround the central enclosed place of worship and support the low-pitched gabled roof with its decorated pediment. With a much revised interior construction, this basic plan was subsequently adopted by European architects in the early 19th cent as a suitable framework for town halls or important public buildings. Greek architecture rose to prominence at the end of the 18th cent. in Britain when discoveries of archaeological remains by travellers and antiquarians on the Grand Tour stimulated its revival. Greek temples and their decorative devices became the models for churches, country houses and government buildings. However, the enthusiasm was relatively short-lived and Roman models took the place of Greek.

Famous Surviving Examples.

Some of the finest examples of surviving Greek temple buildings include: the Temple of Poseidon, Paestum (*c.* 460 B.C.), the Theseion, Athens (449–444 B.C.) and the Parthenon, Athens (447–432 B.C.), while the Theatre at Epidauros (*c.* 350 B.C.) and the restored Stadium at Athens (*c.* 160 A.D.) provide instances of other building types.

ROMAN ARCHITECTURE

As well as designing a wide range of building types, the Romans, like the Greeks before them, were responsible for devising an important set of architectural rules and orders. From the Greeks they adopted the three orders of pillar and beam construction (Doric, Ionic and Corinthian) which they modified to suit themselves and added a further two of their own—Tuscan Doric and Composite. Corinthian and Ionic capitals combined.

In practice, their most popular liking was for the Tuscan Doric (a slim, unfluted shaft with a simple capital and base) and the Corinthian (a richly adorned capital decorated with acanthus leaf motifs and often supported by a fluted shaft). But in a manner unknown in Greece, the Romans frequently applied their orders to what was in essence a pier and arch structure—superimposing orders on top of one another to form the outer walls of a two- or three-storey building. Engineering techniques advanced further under the Romans, principally the introduction of the arch, which allowed them to extend the structural possibilities available to architects. Temples, villas, public buildings and forts are characteristic of the Roman occupation of Britain and it is a tribute to their sound construction that many survive at a variety of sites throughout the country.

Examples of Roman Architecture.

Villas have been preserved at Verulamium (St. Albans). Chedworth in Gloucester. Bignor in Sussex, and at Lullingstone, while the Aquae Sulis at Bath is a splendid public bath and spa. Military garrisons and forts include Corstopitum (Corbridge, Northumberland), Burgh Castle. Great Yarmouth, while a fort on Hadrian's Wall survives at Borcovicium (Housesteads. Northumberland). There is a splendid Roman palace at Fishbourne, near Chichester, discovered in 1960.

As in the case of Greek architecture, Roman buildings, their orders and rules were studied, reproduced and used as the basis for Western architecture from the Renaissance onwards. Their importance lies for British architecture, therefore, not so much in themselves but as an inspiration for others at a time when engineering and building techniques were more advanced, allowing architects to develop classical principles to lengths undreamed of in ancient Greece and Rome.

ROMANESQUE ARCHITECTURE

Romanesque architecture in Britain corresponds with the rule of the Anglo-Saxon and early Norman kings, the period from the departure of the Romans in the 4th cent. A.D. until the dawn of Gothic building in the latter part of the 12th. Because of its very age and the fact that most buildings were constructed from timber, Anglo-Saxon architecture has few representatives in England today. The soundest—their small solid stone churches—have proved the most durable. Towers at Earls Barton and at Sompting and churches at Bradford-on-Avon, Wiltshire, Boarhunt, Hampshire and Worth, Sussex are among the few surviving examples of Saxon building. Characteristic features include rows of plain round-arched windows, pilaster strips forming simple decorative patterns, thick ragstone or rubble walls, small openings and plain arches.

Norman Castles and Cathedrals.

Under the Normans, a particularly warlike race, architectural building extended to embrace castles, though a number of fine cathedrals and churches were also built. All are typified by the plain roundarch. Columns, circular in cross-section, and decoration generally were simply executed with no apparent reference to classical architecture. These were solid, soundly engineered structures with little pretension to style. Because of the tendency to rebuild or enlarge castles and cathedrals not many examples have survived: there are, however, a few which are outstanding: the White Tower at the Tower of London (1086-97), Castle Hedingham, Essex (*c.* 1140) and Orford Castle, Suffolk (1166–72) all of which consist of a central keep set on an artificial mound and surrounded by earthworks.

In the ecclesiastical field, the nave of Durham Cathedral (1110–33) has splendid dog-tooth decorated columns and arches; other predominantly Norman cathedrals include Norwich and Chichester, while the naves at Rochester, St. Albans, Chichester, Hereford, Peterborough and Ely all include Norman building. As with the castles, they are massively constructed from stone.

GOTHIC ARCHITECTURE

The architecture of the Middle Ages, whose most characteristic feature was the pointed arch, is said to have spanned the 13th to the 15th cents. Gothic building is essentially a structural system based on arches, piers, vaults and buttresses arranged and decorated to an overall plan. In the absence of great Gothic castles or private houses, the system was most fully developed and seen to best effect in cathedrals and monasteries in mediaeval Britain.

The Three Main Periods.

Following a transitional phase from *c.* 1150 to 1190 when, for example, pointed arches were introduced into structures otherwise Romanesque in character, Gothic architecture has traditionally been divided into three periods: **Early English**, 1190–1310, occasionally known as the lancet style from the typical shape of the long narrow windows, **Decorated**, 1310–1380, where the degree of decoration is heightened, window tracery being symmetrical in form or "Geometrical", followed by a period of increasingly complex and more flowing patterns called "Curvilinear", and finally the **Perpendicular** phase, 1380–1485, when the term "Rectilinear" is used to describe larger windows divided by horizontal tracery members or transoms.

While good examples of each of these three phases and their intermediate transitional phases survive in Britain, it is often possible when visiting a large cathedral to distinguish them all exhibited in various parts of the same building. Cathedral construction took many generations and as architects and masons were succeeded so new ideas of design became incorporated in the overall plan. The progressive expansion and re-building of Canterbury Cathedral throughout the mediaeval period has meant that it is possible to see here most styles of building from Norman through to Perpendicular; the same may also be said of York and Worcester.

However, Salisbury Cathedral (1220–65) was almost wholly constructed in the Early English period and remains one of Britain's most complete and coherent designs. Lincoln too is mostly Early English with Decorated additions.

Improvements in Structural Techniques.

In general it is possible to say that as structural techniques improved in the Middle Ages, the massive character of the Early English period gradually gave way to thinner walls, more complicated and loftier vaulting supported by splendid buttresses, increasingly ornate collections of columns and capitals, more elaborate tracery in larger windows filled with vivid stained glass pictures and a greater concern with surface ornament. Towers are late Gothic features and they, in common with the building below, assumed the decorative characteristics of the Perpendicular phase, replacing the spires which had dominated the Early English and Decorated churches and cathedrals.

The Castles of Wales.

Generally speaking castles became less buildings of war and more country houses as the Middle Ages passed. The Early English period corresponded under Edward I with a great castle building era in Wales and produced possibly the finest defensive garrisons of the time. Harlech (1283–90) and Beaumaris (1283–1323) both have solidly built rings of battlemented and turreted wall, allowing the defenders to retreat into progressively more solid and awesome towers for a last-ditch defence. Bodiam Castle (1385), built in the following cent., only boasts an outer wall though it is surrounded by a moat; the living conditions are more spacious and less care is taken to see that they are protected. Finally Oxburgh Hall (1482), a 15th-cent. manor house, has virtually given up all pretence of being a castle, retaining only the square plan and central courtyard in its design. Although the outer walls are solidly built, there are no proper battlements or turrets, the living quarters forming the square plan. Still not quite a country house, Oxburgh Hall indicates that the day of the castle, though not the garrison, had largely passed.

TUDOR ARCHITECTURE

The architecture of the Tudor monarchs (from Henry VII's accession in 1485 until Elizabeth I's death in 1603) witnessed for the moment the penultimate phase of Gothic building and the flowering of the country house. While European architects and particularly those in Italy were re-discovering classical antiquity, Britain, which had recently left the Papal fold, was pursuing a severely national or vernacular line (*q.v.*) Tudor architecture was essentially Perpendicular Gothic modified in places by a few graftings from the Renaissance in Italy.

A strong accent was placed on local building styles and materials. Where stone was unavailable patterned bricks became common, featuring as finely decorated chimney stacks, which contrasted pleasantly with drip-mould windows and doorways. Leaded lozenge windows emitted light into linenfold panelled rooms.

Houses increased in size with the addition of summer and winter parlours, studies, bedrooms and for the first time, state rooms, like the great chamber and the dining chamber. Hampton Court Palace (*c.* 1520) provides an excellent example of Tudor building on a grand scale constructed from red brick with stone dressings, oriel windows over the gateways and finely carved chimneys. Barrington Court (1518) is a smaller country house with individual Gothic features treated in a very English fashion: square-headed windows with mullions and transoms, sharply pitched roofs and gables and a symmetrical plan with a central porch

Elizabethan Country Houses.

In the Elizabethan period houses were generally constructed on the E plan with the central porch forming the third bar between the two wings. However, fine stone country houses, square in plan built around a central courtyard, include Longleat House, Wiltshire (1567–80) and Wollaton Hall, Nottingham (1580–88) designed by Robert Smithson (*c.* 1536–1614), while Montacute House, Somerset (1580–99), and Pitchford, Shropshire (1560–70) are based on the E plan. In this later period elevations showed a greater unity and symmetry then before and were lit by much broader areas of window.

The central feature of the façade was often a two-or three-storey porch or pavilion decorated with strapwork ornamentation and topped by a pediment containing a Gothic coat of arms. The porch at Kirby Hall. Northampton (1575) shows French inspiration, that at Cobham Hall, (1594) Flemish.

JACOBEAN AND STUART ARCHITECTURE

The Jacobean period (1603–25) witnessed the final phase of Gothic building in England before it was revived in the late 18th cent. Designs tended to be simpler and more restrained than under Elizabeth and exhibited a growing tendency to employ Italianate ornament rather then Gothic. Symmetrically arranged in traditional fashion, the following houses are representative of the Jacobean period: Hatfield House, Hertfordshire (1607–11) designed by Robert Lyminge, Bramshill, Hampshire (1605–12), Audley End, Essex (1603–16) and Charlton House, London (1607–12). In a sense this was a transitional phase between the English vernacular Gothic of the Tudor period and the influence of the Italian Renaissance under Jones and Wren. In their restraint, the great Jacobean houses have a classical feeling but in the retention of many late mediaeval features, such as mullioned windows and turrets they justify the contemporary appelation "King Jamie's Gothic".

The Work of Inigo Jones.

By contrast the Stuart period (1625–1702) by admitting the influence of European architecture, produced one of the richest periods in English building. Its first leader was Inigo Jones (1573–1652) designer of the Queen's House, Greenwich (1616–35) and the Banqueting Hall, Whitehall (1619–22) together with a large number of country houses.

Jones began life as a designer of scenery and costumes for court masques but having made two visits to Italy to study the work of Palladio, he brought back to England a pure Italian Renaissance style which was then of a wholly new character. Putting his knowledge and ideas to work as Surveyor-General of Works to the Crown in his two seminal designs, the Queen's House and the Banqueting Hall, Jones's work through the influence of Palladio marked a return to classical models so long ignored in Britain. However, because of the original and startling nature of these two designs, his influence was not immediate and most early 17th-cent. country houses are Jacobean rather than classical in style.

Sir Christopher Wren.

Sir Christopher Wren (1632–1723), who focused his attentions on church builing, followed in Jones' footsteps as the architectural leader of the latter part of the cent. St. Paul's Cathedral (1675–1710) forms the centrepiece of his work in rebuilding London's churches after the Great Fire of 1666, while St. Martin Ludgate (1677–84), St. Clement Danes, Strand (1680 82) and St. Mary-le-Bow, Cheapside (1670–73) should not be forgotten, He also designed the additions to Hampton Court Palace (1689 94), Chelsea Hospital (1682–91) and Tom Tower, Christ Church College Oxford (1682).

With the exception of the latter, these buildings clearly derived their influence from the Italian Renaissance, obeying its rules of construction as well as using its orders. Unlike Jones, Wren succeeded in developing the style in such a way—by drawing on French and Dutch examples as well and by inclining it towards the Baroque—that he produced a distinctly English version of classicism. His structural skills were remarkable as demonstrated by his masterly use of traditional materials and by the Portland stone which he introduced to London where it became so popular.

English Baroque.

Towards the end of the cent and in the early years of the 18th cent. there developed a new and more vigorous form of classicism—the so-called English Baroque. Rules and conventions were ignored or bent to achieve arresting affects of grandeur, richness and movement. The leaders of this movement were Wren's pupil Nicholas Hawksmoor (1661–1736) and Sir John Vanbrugh (1664–1726), men who no longer felt constrained by the self-imposed discipline of their predecessors. Plan and details were handled with great confidence, featuring twisted and rusticated columns, elaborate curved entablatures and pediments accompanied by a great display of ornament and sculpture of abounding vitality.

These buildings were constructed on a grand scale such as Vanbrugh's Blenheim Palace, Oxford (1704–20) and Castle Howard, Yorkshire (1699–1712), while Hawksmoor designed parts of All Souls (1715–40) and Queen's College, Oxford (1709–38).

PALLADIAN ARCHITECTURE

Following the vigorous and expansive Continental treatment of buildings in the Baroque period, English architects moved towards a more restrained approach. For their guide they selected Colen Campbell's *Vitruvius Britannicus*, a folio of engravings of classical buildings in Britain, first appearing in 1715. This represented not only a return to British examples, but also a return to a rational system of architecture, where restraint, order and symmetry were paramount. Andrea Palladio's (1508–80) classical villas formed a second major source for English architects. For example, Lord Burlington's villa. Chiswick House (begun 1725), was a scaled-down version of Palladio's Villa Rotunda at Vicenza (1550 53), while Campbell's design for Mereworth Castle, Kent (1723 -25) was a slightly enlarged interpretation. The Palladian movement, taking its name from Palladio, represented a fresh devotion to antiquity, not necessarily antiquity as it really had been, but as Englishmen now viewed it.

Palladian Country Houses.

The Palladian movement probably found its finest expression in the country house. Its characteristic features include: a strictly formal three-part grouping, comprising a central block with pedimented porch or portico and two widely spaced symmetrical wings connected to it by single-storey passages, screens or colonnades. The basement floor is usually rusticated and forms a plinth to the Giant Order which extends through the two principal stories of the façade to a decorative entablature. Restraint in the use of ornament, with stress on order and proportion, characterise these cleanly executed stone houses. It was a patriotic movement drawing on the designs of Inigo Jones, who in the early 17th cent. had first been responsible for the introduction of this interpretation of Italian Renaissance architecture.

The Typical Town House.

The Palladian schema was also readily applied to the town house. Usually three storeys high, these restrained brick buildings were despised by the Victorians for their simplicity and lack of stylistic variety and ornament. The ground and second floor windows were usually of roughly the same size (the former being slightly larger), while the first floor had the largest, demonstrating its importance—here were the dining and reception rooms. The top floor had the smallest, partly as they lit the servants' quarters, but also to bring the upward movement of the eye to a halt beneath the entablature, above which there might be an attic. There was normally a minimum of adornment, being limited to the columns placed at the entrance or the cast-iron railings around the steps and pavement.

THE GREEK REVIVAL

Although the Palladian movement was classical in origin, it largely confined itself to Roman models. The development of the study of archaeology and a rising interest in Greek civilisation, made available a growing volume of material for architects interested in classical buildings. Although Greek archaeological discoveries were being made in the mid-18th cent. Greek architecture did not become fashionable until the 1790s and experienced a fairly short-lived popularity, falling from favour in the 1830s, though certain architects, such as Alexander "Greek" Thomson (1817–75) in Glasgow, did revive its use in the latter part of the 19th cent.

Like the Palladian movement, the Greek Revival stressed symmetry, order and proportion, but was responsible for introducing a new range of architectural features. The Greek Doric and Ionic orders were adopted, while their entrances and window surrounds superseded the Roman arch. Greek details were used for decoration, including echinus moulding, key and disc string courses *etc.*

The Work of John Nash.

One of its greatest exponents, though not a purist, was John Nash (1752–1835) who was responsible for re-building the main thoroughfares between Regent's and St. James's Park. His London Park Crescent (begun 1812) features a splendid sweep of coupled Greek Ionic columns, while Cumberland Terrace (1827) has a central Ionic portico and pilasters arranged in the Giant Order. Sir Robert Smirke (1780–1867) similarly resorted to the Greek style for his Covent Garden Theatre (1808 -09, burnt down 1856), and General Post Office (1824–29, demolished 1913), while W. and H. W. Inwood's St. Pancras Church (1819–22) exhibits a full range of Greek features including a low-pitched Ionic portico and classical statues supporting the aisles.

THE GOTHIC REVIVAL

The Gothic Revival, like the Greek Revival, had its origins in the awakening interest in archaeology and British history. Unlike Palladian buildings, Gothic was founded in the philosophy of the "Picturesque". In a sense its principles were the very opposite of those encompassed by notions of classical beauty. The picturesque derived its appeal from an asymmetrical arrangement of differing forms and it was this sense of variety and surprise which gave it interest. Its features, which were supposedly selected from England's medieval past, included the pointed arch, tracery, buttresses, towers, turrets and battlements, *etc.*

Although Gothic gained a certain acceptance in the latter part of the 18th cent. (Horace Walpole's (1717–97) house. Strawberry Hill, Twickenham was built from 1748 onwards), it did not gain wide popularity until the decline of the Greek Revival when Romantic thought had triumphed over Enlightened opinion, and rules had been replaced by passions.

The Contribution of Pugin.

Before the 1830s most Gothic buildings, though dressed in 14th-century clothes, had conformed to symmetrical classical plans and were scarcely truthful representations of their mediaeval counterparts. The move towards a more genuinely picturesque interpretation was publicised by A. W. N. Pugin (1812–52). A practising architect himself, Pugin wrote a series of studies extolling the virtues of Christian architecture. Although mostly concerned with churches, his principles were taken up and developed to cover other building types. Essentially, he argued that function should dictate design not pre-conceived classical rules, and that buildings should be constructed in a moral style (for him, English Gothic) which alone had the ability to elevate the population. By publicising Gothic (Pugin together with Charles Barry were responsible for the design of the Houses of Parliament, from 1837). Pugin paved the way for the "battle of the styles" that was to break out in the mid-19th cent.

NEO-CLASSICAL ARCHITECTURE

Having seen that the Greek Revival was based on a re-discovery of antiquity, the same is also true of the Neo-Classical movement. Following the Palladian tradition, there arose a fresh interest in Italian Renaissance building, though no longer treated in a rigid and severely ordered fashion. Romanticism had supplanted the Enlightenment and men felt that the free flow of the passions had more to offer than pure reason. The Greek Revival was followed in the 1840s and '50s by a Graeco-Roman phase of great magnificence used for public buildings such as the St. George's Hall, Liverpool (1840–54) by H. Lonsdale Elmes (1814–1847), and the Fitzwilliam Museum, Cambridge (1837–47) by George Basevi (1794–1845), although both were actually completed by C. R. Cockerell (1788–1845). Although most of these buildings were Roman in inspiration, in some later examples architects no longer felt bound to distinguish between Greek and Roman models and used forms of decoration for each civilisation, no longer rigorous in their obedience to tradition.

The Genius of Soane.

The leaders of the Neo-Classical movement were Sir Charles Barry (1795–1860) and C. R. Cockerell, though it would be wrong to omit the original genius of Sir John Soane (1753–1831) from any consideration of British architecture. Not strictly speaking a Neo-Classicist, Soane's very originality makes him difficult to categorise, but he probably occupies a transitional position between the rigid Palladian schema and the greater freedom and adventurousness of the Neo-Classicists. He evolved a personal style that blended Baroque grandeur of composition with a Grecian severity of detail. Although not prolific in output, his austerity, crisp lines, simplicity of surface and feeling for cubic relations and space, were all manifested in his own house, No. 13 Lincoln's Inn Fields (1812–13), now the Soane Museum. Unfortunately his finest work at the Bank of England, the Bank Stock Office (1792–93) and the Dividend Office (1818–23) were both demolished in 1927.

Barry and Cockerell.

But to return to Barry and Cockerell, the former is perhaps best known for his design of London clubs: the Travellers (1829–31) and its neighbour the Reform (1837–41) are his finest. Barry used Italian Renaissance palaces (adapted from originals in Florence and Venice) for his designs and this resulted in the use of the term "palazzo" style. In contrast with the earlier Palladian movement (and offering certain similarities to the work of Inigo Jones), Barry's designs were not as tightly restrained by classical rules of proportion and construction but influenced by Romanticism and hence were more vigorous, lively and plastic than 18th-cent. palace designs. Other good examples of Neo-Classical architecture include the Free Trade Hall, Manchester (1853–54), by Edward Walters (1808–72), Barry's Athenaeum, Manchester (1837–39), the Bristol branch of the Bank of England (1844–46) and the Liverpool branch (1845–58) both by C. R. Cockerell.

THE HIGH VICTORIAN MOVEMENT

In many ways the High Victorian movement represented an extension of Pugin's principles, a romantic development of his views. Its leaders were John Ruskin (1819–1900), who never designed a single building and William Butterfield (1814–1900), who never wrote a single treatise. As writer and architect respectively, they publicised and practised the art of High Victorian building. Ruskin argued in the *Seven Lamps of Architecture* (1849) and the *Stones of Venice* (1853) that the finest examples of Mediaeval Gothic architecture were to be seen in the great Italian cities of Venice and Florence. Their aristocratic and mercantile palaces, together with the splendid churches and cathedrals, provided the models for Ruskin's theories. He believed in vigorous and powerful designs—on balance, he suggested, Pugin's many churches lacked mass and power—and in a sense he succeeded in synthesising Burke's views on the sublime with those of Uvedale Price and Pugin on the picturesque. Ruskin applied the sublime notions of scale, mass and awe to the Venetian Gothic of mediaeval Italy, while Pugin preferred Early English as a morally purer style; Ruskin and the later Victorians were more eclectic and went abroad for their inspiration.

Ruskin and his supporters also believed that buildings should be constructed from polychrome materials, and executed by the most skilled of craftsmen. Multi-coloured stones, the use of different coloured bricks and terra-cotta, providing that they were not machine-made or moulded, were the hall-marks of their buildings. The skills of the Christian craftsmen eulogised in Ruskin's writing were later to be selected and used as the basis for the Arts and Crafts movement by William Morris and his followers.

High Victorian Churches.

One of the first High Victorian churches was Butterfield's All Saints, Margaret Street, London (1850–59), whose richness and powerful design was later surpassed by his designs for Keble College, Oxford, where the magnificent chapel (1867–83) formed the centrepiece. Although originally applied to churches, High Victorian Gothic was felt to be almost universally applicable to all building types—a style for the period, again in contrast to Pugin's Gothic. Indeed some of the most successful buildings of the time were its public buildings—clear expressions of Victorian society—such as town halls, museums, public libraries, universities, mechanics' institutes, workhouses and prisons. Councils who commissioned them saw these structures as permanent expressions of their pride and status, sparing no expense on their construction and adornment. Alfred Waterhouse (1830–1905) designed Manchester Town Hall (1868–77), the Albert Memorial, London (1863–72) and the Prudential Assurance Building, Holborn (1878–85): Sir George Gilbert Scott (1811–78), another great exponent of High Gothic, designed St. Pancras station and hotel (1868–74) and Glasgow University (1868–71).

The Battle of the Styles.

These examples are, of course, all Gothic but it ought to be remembered that the High Victorian period corresponded with the so-called "battle of the styles". This resulted from the continued popularity of Italianate architecture producing a division in popular taste. As Gothic became more elaborate in ornament, open to foreign influence, and richly executed, so Italianate buildings received similar treatment. Scott's Foreign Office buildings, Whitehall (1860–75), and Cuthbert Broderick's (1822–1905) Town Hall, Leeds (1853–59), a grandiose example of High Victorian classicism, are instances of the continued popularity of Italianate or Roman models, while the National Westminster Bank, Bishopsgate, London (1865) by John Gibson is classical rather than Gothic in inspiration.

EDWARDIAN ARCHITECTURE

In some senses Edwardian architecture may be viewed as a reaction to the highly ornate and richly executed Gothic of the Victorian period. As before, no one style came to the fore and the period was characterised by a number of revivals often executed in a more simple if equally exuberant and confident manner. For house building, small office blocks and flats, the Queen Anne style was judged to be appropriate, while for public buildings, city offices, department stores and important monuments, the Renaissance and Baroque styles of the 17th cent. were adapted to suit modern conditions.

Examples of Baroque include Selfridges Store, Oxford Street (1907–09) whose façade was designed by the American architect Francis Swales, and Colchester Town Hall (1897–1902) by John Belcher (1841–1913), while Renaissance designs include Ralph Knott's London County Hall, on the South Bank (1912–22) and Sir Edwin Lutyen's (1869–1944) Britannic House, Finsbury Square (1926).

Although these buildings were technically quite advanced they were constructed using the new steel framework, the first English building of this type being the Ritz Hotel, Piccadilly (1905–06) by Mewes and Davis—their façades, unlike contemporary American buildings, did not reflect their modern internal structure but concealed it beneath styles adapted from former ages. One of the few buildings to reflect its internal framework in a modified classical façade was Kodak House, Kingsway, London (1910–11) designed by Sir John Burnet (1857–1938).

New Sources of Inspiration.

Those architects who did not necessarily draw on the past for their inspiration found two other developments of interest: Art Nouveau and the Arts and Crafts movement (*see* **N3**). The former was a style of decoration and building chiefly founded on the Continent, coming to the fore between 1890 and 1910 when it was adopted in Britain by Arthur Mackmurdo (1851–1942), the Scottish architect, and Charles Rennie Mackintosh (1868–1928), designer of the Glasgow School of Art (1897–1909). These architects not only designed the outward form of their buildings but also took responsibility for their interiors, fixtures and fittings. Characteristic art nouveau shapes included hearts, lilies and other stylised flowers linked together with flowing materials and stems.

The Arts and Crafts Movement.

The Arts and Crafts movement, which was closely related to the more European art nouveau, led by William Morris (1834–96) and Philip Webb (1831–1915) was in part a development of Ruskin's views. They passionately believed in the traditional skills of the craftsman and attempted to use his abilities and designs as the basis for their house and church building together with their contents. One of the movement's most successful exponents was C. F. A. Voysey (1857–1941), a disciple of Norman Shaw and Morris. As a house designer he went some way towards breaking with the past by discarding definite period styles, such as Queen Anne then so popular among other English architects, for a "free traditionalism" based on old English cottage and farm house vernacular. Working with traditional materials—timber, tiles, bricks, leaded windows and stone—he introduced a fresh note of simplicity and naturalism, a personal style that was plagiarised in the inter-war period when vast sweeps of suburban Britain were constructed.

Norman Shaw.

The Edwardian era was a particularly eclectic period when architects felt free to design buildings in a number of styles derived from a variety of sources. No one illustrates this trend better than Norman Shaw (1831–1912). New Scotland Yard, London (1887–88), typically constructed in red brick and white Portland stone has fenestration which follows a regular Queen Anne pattern, enlivened by the addition of Scottish baronial corner turrets, with Baroque finishes to the gables and entrances. His last major work, the Piccadilly Hotel, London (1905–08) is a splendid expression of Neo-Baroque featuring a central open Ionic colonnade supported by a vigorously rusticated arcade flanked by flowing gabled wings.

THE MODERN MOVEMENT

In sharp contrast to the Arts and Crafts movement and indeed to almost all that had gone before, modern architecture as it developed in the early years of the 20th cent., was based on a break with historical tradition and founded on a functional approach to the fullest use of new building materials and engineering techniques. Not since Joseph Paxton's (1803–65) use of iron and glass in prefabricated sections in the design of the Crystal Palace (1850–51), had such an original course been pursued.

The First Advances.

The first real advances in modern architecture, however, did not occur in Britain but in America, France and Germany. The French had pioneered the use of reinforced concrete. The Americans, particularly Louis Sullivan, in Chicago and New York designed towering sky-scraper blocks made possible by the use of the steel skeleton, while in Germany Peter Behrens (who designed the Turbine Factory, Berlin, 1909) and his pupil Walter Gropius (designer of the Fagus Factory, Alfeld-an-der-Leine, 1911–14) when commissioned to build prestigious factories, were among the first to use these materials as originally as they could by concentrating on forms and the devastating effects they could achieve by exploiting their technical strengths.

The Inter-War Years.

Britain was slow to follow in their footsteps and there are not many fine examples of modern architecture to be seen dating from the inter-war period. The exceptions include Sir Owen Williams's Chemical Factory for Boots at Beeston, Notts (1930–32) which made startling use of reinforced concrete and glass based on a cantilevered structure. The Shakespeare Memorial Theatre at Stratford-upon-Avon (1928–34) was constructed from brick with very little reference to any historical styles, while Peter Jones's Store in Sloane Square, London (1935–36) exhibited the original use of glass in an articulated façade, the use of a steel frame construction allowing maximum floor space and free circulation. The Finsbury Health Centre, London (1938–39) has a concrete frame and façades faced with glazed tiles, the windows of the two-storey wing blocks, that frame the central entrance building, being linked vertically with opaque glass panels.

THE POSTWAR ERA

The plan of a modern building is not preconceived in the way that a Palladian country house would, for example, have symmetrical wings and central entrance portico, but good modern architecture evolves from a study of the proposed function of a building and the needs of the occupants. Its shape should emerge, therefore, as the architect discovers more about its role. Elevations develop organically from the plan and reflect the inner plan externally. There has been an emphasis on economy, not only on utilitarian grounds, but because the trend has been against applied decoration, in part simply a reaction to what had come before—the Edwardian period had already witnessed a refinement and reduction in the degree of ornamentation. An important development was the increased use of prefabricated materials in modular designs. Reinforced concrete or steel columns and beams form the strong framework to which are attached pre-cast wall and window units to form standard-sized cubes and rectangles.

Post-War Failings.

However, much that was built in Britain in the 1960s and 1970s, when the economy was expanding and there were political pressures on architects and planners, even failed to live up to the criteria laid down by the earlier thinkers on modern design.

Many of these buildings did not take proper account of their occupants' needs; tower blocks though often successful as offices or hotels proved unsuitable for families as homes and created more problems than they solved.

Unfortunately insufficient research was undertaken into the long-term performance of new building techniques and materials. The Ronan Point disaster in 1968, when part of a tower block collapsed like a pack of cards, revealed the inadequacy of some types of system building, while other buildings subject to ten years' weathering soon became blackened, lost parts of their tile façade or did not stand up to the test of continuous use. Often bland, repetitive and unimaginative in their exteriors, many cost-effective modern buidlings are far from aesthetically satisfying. Too many examples of modern architecture are inherently brutal, dull and unsatisfying. However, there are some buildings which certainly deserve attention and judged against the best from the past would be of comparable merit. Coventry Cathedral (1951–1962), the Festival Theatre. Chichester (1962) and the Playhouse, Nottingham (1964) are good examples.

High Tech and Deconstructivism.

The term Late Modernism is used of the architecture of the period from 1945 to *c.* 1970 (in Britain the term Contemporary Style refers to the years 1945 to 1956 in particular). For the more recent period the terms Corporate Modernism and High-Tech Architecture obviously reflect the luxury office blocks of the great multi-national companies. Deconstructivism (used of the period after 1980) emphasises the bending of traditional building frames and the distorting of the old rectilineal concepts of building.

Other features of recent architecture are the vastly increased use of computer-aided design and an increasingly international desire to strip buildings of much of their ornamentation.

Some notable architectural developments include the Tate Modern, Norman Foster's Jubilee Line station at Canary Wharf and the National Botanical Gardens in Wales. Foster's other work includes the Great Court in the British Museum and Chep Lap Kok airport in Hong Kong, The new century is continuing this era of innovation. There is also an urge to build higher and higher skyscrapers (*see* **L100**), such as The Shard in London (completed in 2012). This was conceived by Renzo Piano whilst Cesar Pelli designed One Canada Square in Canary Wharf. The Lloyds Building and the Cheesegrater were designed by Richard Rogers.

Mention must also be made of the national showpieces designed by Zaha Hadid–China's Guangzhou Opera House, Spain's Bridge Pavilion in Zaragoza *etc*.

GLOSSARY OF ARCHITECTURAL TERMS

Abacus. The thin slab forming the upper member of a capital (*see* illustration of orders).

Acanthus. A form of curved ornament based on the leaves of the acanthus plant, native of south-eastern Europe. The leaves were stylised by Greek sculptors of antiquity to form the characteristic ornament of Corinthian and Composite capitals and on mouldings generally.

Acroterion. A block of stone resting on the top or at the end of a pediment to support a figure or carved ornament.

Aisle. An open space in a church running parallel with the nave.

Alcove. A recessed space in a wall, usually vaulted and originally the place for a bed.

Anthemion. A characteristic Greek form of ornament based on the honeysuckle flower and leaves.

Apron. A raised panel, sometimes shaped and decorated immediately below the sill of a window.

Apse. A semi-circular extension at the eastern end of a church.

Arabesque. A flowing interlaced type of ornament based on complex geometrical patterns, originally devised by Arabian artists.

Arcade. A row of arches supported by columns, either part of a building or free standing.

Arch. An arrangement of wedge-shaped masonry or bricks arranged in a semi-circle and usually supporting the weight above.

Architecture. The art and science of building. The provision of shelter for mankind by the orderly arrangement of materials in a manner which expresses man's attitude to living. Until the last 150 years structural methods were limited to timber frames, columns, lintels, load-bearing walls, arches, vaults, and domes in brick or stone.

From these few basic elements have evolved the great variety of historic styles of building to be found throughout the world. To give but one example, the Greeks created those systems of decorated columns and beams, known as the Orders, which were adapted by the Romans, revived decoratively rather than structurally during the Renaissance and are still used in debased form on the more presumptuous type of modern building.

This, and the development of new structural techniques and materials (steel, aluminium, sheet glass, reinforced concrete, plastics and plywoods, to name a few), have made the interest in historic styles of less importance.

Modern architecture is the creation of buildings with the highest possible standards of functional performance in terms of efficient planning and structure, good lighting, adequate heating *etc*.

Architrave. The lowest division of an entablature, a moulded lintel between two columns (*see* illustration of orders).

Arrow Loop. A vertical slot formed in the walls or battlements of a castle or fortification through which archers could fire their arrows.

Bailey. A court in a fortified mediaeval castle, lying between the outer walls and the keep.

Balustrade. A railing consisting of a series of balusters, an individual column, supporting a continuous horizontal member.

Barbican. A small tower or fort built outside a castle to form the first line of defence.

Bargeboard. Carved woodwork covering the joint between a gable end and the roofing material forming an overhanging verge.

Barrel Vault. A continuous arched roof or ceiling of semi-circular form.

Bastion. A tower-like structure projecting from the angles of the outer wall or along its length.

Bauhaus. A German institution for the training of architects, artists and industrial designers founded in 1919 at Weimar by Walter Gropius, (d. 1969). It was closed by Hitler in 1933 and re-opened at Chicago. The Bauhaus doctrine held that there should be no separation between architecture and the fine and applied arts; that art, science and technology should co-operate to create "the compositely inseparable work of art, the great building". The original institution, at the instigation of Gropius, included on its teaching staff not only architects and technicians but also such noted artists as Paul Klee and Wassily Kandinsky.

Belvedere. A look-out place such as a turret or high platform on the roof of a house to provide a view of the surrounding countryside.

Blind Arcade. A row of arched recesses in a wall.

Boss. An ornament covering the intersection point of the ribs in a roof.

Buttress. A support against and joined to a wall to strengthen it.

Campanile. A bell tower often detached from the main building.

Cantilever. A beam or slab supported at one end only and counterbalanced.

Cap. The topmost member of the pedestal in a classical order.

Capital. The moulded or sculptured head of a column (*see* illustration of orders).

Coffer (also known as a **caisson**). A recessed panel, usually ornamented in the under-surface of a ceiling, barrel-vault or balcony.

Composite order. A Roman order of architecture which combines the characteristics of the Ionic and Corinthian orders.

Corbel. A strong supporting member, of stone or timber, projecting from a wall to support a beam or other feature.

Cornice. The top division of an entablature.

Cupola. A small dome-like roof or lantern. An ornate turret attached to a roof to give light to an interior or to contain a bell.

Dentil. A small square block used in series for ornamentation in Ionic and Corinthian cornices.

Dormer. A window that projects from a sloping roof having vertical sides and front.

Dressings. Blocks of stone cut to true plane faces or shaped for use as quoins or keystones.

Dripmould or Dripshone. A Gothic moulding shaped to throw water clear of the door or window below following the curve of an arch.

Eaves. The lowest part of a roof, overhanging the top of a wall.

Egg and Dart. Patterns carved on an ovolo moulding based on the design of eggs and arrow-heads arranged alternately.

Engaged Column. A column apparently partly embedded in a wall, also known as attached columns.

Entablature. The upper part of an order, consisting of the architrave, frieze and cornice.

Entasis. The slightly convex curve to the side of a column, formed in order to counteract the optical illusion of the outline being concave should the sides be straight.

Finial. A carved or moulded ornament which crowns a pinnacle, gable or spire.

Fluting. Shallow, rounded grooves applied to any surface but often to the shaft of a column.

Frieze. The member of an entablature between the cornice and the architrave, frequently ornamented in all orders except the Tuscan.

Functionalism. *See* **N7**.

Gable. The triangular wall surface formed by the meeting of two sloping wall lines at the end of a ridged roof.

Hipped Roof. A pitched roof, the end of which is also sloped back, meeting the sides in a pair of hips.

Keep. The great tower or innermost stronghold of a medieval castle.

Key. The central voussoir (*q.v.*) of an arch, sometimes ornamented with carving, situated at the crown of the arch.

Lancet. A tall narrow, sharply pointed Gothic window, a feature of the Early English style.

Lantern. A small ornamental open or glazed turret on a roof or dome to light or ventilate the interior.

Linen-fold Panelling. A decorative device of folded linen used on panelling and furniture in the Tudor period.

Lintel. The horizontal member, supported at each end, which spans two columns.

Lunette. A semi-circular (or circular) window.

Machicolation. The holes between the corbels of a projecting parapet through which missiles were dropped in a mediaeval castle. Later the design was used for purely decorative purposes.

Mansard Roof. A form of pitched roof with two slopes on each side to increase the space inside, the upper slope being steeper than the lower.

Mullions. The vertical bars dividing the lights in a window, forming a highly decorative feature in the Tudor period of English Gothic architecture. The cross-beam or horizontal bar of wood or stone in a mullioned window is styled a transom. *See* **Windows, Section L.**

Nave. That part of a church between the choir and the western entrance, separated from the aisles.

Obelisk. A tall stone pillar with four tapering sides and a pointed pyramidal top.

Ogee. An "S"-shaped curve featured in an arch.

Order of Architecture. A column with a base, shaft and entablature. The orders evolved by the Greeks were Doric, Ionic and Corinthian. The Romans added the Tuscan and the Composite.

Oriel Window. This is a window projected from the front of a building, rectangular, triangular, or pentagonal. The ordinary bay window and bow window are varieties of Oriel. When an Oriel window does not reach to the ground it usually rests upon moulded sills supported by corbels.

Ovolo. A small convex moulding.

Palmette. A stylised leaf ornament, said to resemble a palm leaf.

Parapet. A low wall at the edge of a roof, generally formed by an upward extension of the wall below, often enlivened by sections of balustrade (*q.v.*).

Pargetting, Parging. The plastering of a wall or ceiling and often patterned or decorated by scratching or modelling in low relief in the plaster coating.

Pediment. The triangular low-pitched gable end of a Greek or Roman temple. Pediments are often also used for decorative purposes over windows or doors when they may be either angled, curved or broken, the latter when the apex of the triangle is omitted and replaced by ogee curves ending in scrolls with an ornamental feature inbetween.

Pilaster. A rectangular column, projecting slightly from the wall and conforming to the design of the orders.

Porch. A roof structure forming a small room to shelter the entrance of a house.

Porte-Cochère. An entrance porch for carriages to a house from the street allowing people to alight from the vehicle and enter under cover.

Portico. An imposing kind of porch in the Classical manner consisting of a low-pitched roof supported by columns, finish with a triangular pediment and often approached by a flight of steps.

Quoin. The emphasised bricks or stones at the angle of a building.

Relieving Arch. An arch constructed above a square-headed opening in a wall, relieving the lintel or beam over it from some of the weight above.

Rotunda. An isolated building, circular in plan, often with a domed roof.

Rusticated. When the joints between stone or brick are emphasised by deep grooves or channels to impart the impression of strength or massiveness.

Segmental Arch. An arch in which the contour is a segment of a circle.

Soffit. The under surface of an architectural feature, *e.g.* an arch, cornice, window or door head.

Spandrel. The triangular space enclosed by the curve of an arch.

Strapwork. An Elizabethan form of decoration consisting of enriched interlacing bands, generally used on ceilings and occasionally on panels.

String Course. A continuous horizontal band, either plain or moulded, projecting from the face of a structure.

Stucco. External plastering, often moulded and painted to appear like stone.

Terra-Cotta. A hard unglazed pottery ware of fine texture, made from fine brick earth, burnt in moulds and used for decoration or as facing material.

Transom. A horizontal member dividing a window into two rows of lights.

Tympanum. This is, in architectural phraseology, the triangular space at the back of a pediment, or, indeed, any space in a similar position, as over a window or between the lintel and the arch of a doorway. In ecclesiastical edifices the tympanum is often adorned with sculpture.

Venetian Window. A window consisting of three lights, one arched large centre one, and two narrow square-headed side lights.

Vermiculated. A form of rusticated (*q.v.*) masonry where the face of each block is carved with short, irregular wavy channels and hollows.

Vernacular Style. The native way of building, unaffected by classical rules. The Tudor style in Britain was truly vernacular.

Voussoir. A wedge-shaped brick or block of stone forming the components of an arch.

Weather-boarding. Horizontal, overlapping planks of timber, fixed to an internal framework, forming the outside wall of a building.

THE WORLD OF MUSIC

The story of music as it has evolved in the Western world, with an outline historical narrative, a glossary of musical terms and an index to composers. The period covered runs from early secular music through the Renaissance and Baroque, and the glory of Bach and Handel to the vibrant music forms of more recent times. The Section also provides an introduction to some of the most popular dances in Britain, Europe and America.

III. Index to Composers 34–35

IV. Special Topic 36–38

Dance in the West 36

THE WORLD OF MUSIC

In writing this section no special knowledge on the part of the reader is assumed; it is for those who want to know about the history of music, how different styles evolved, and how one composer influenced another. It is a background to music as the science section is a background to science, and just as the latter cannot show the reader the colours of the spectrum but only tell of Newton's experiments and of the relationship between colour and wavelength, so in this section we can only describe human achievements in the world of sound. But knowing something about composers, their work, and when they lived can help to bring fuller understanding and enjoyment when listening to their music.

The section is in four parts:

I. Historical Narrative and Discussion
II. Glossary of Musical Terms
III. Index to Composers
IV. Special Topic

I. HISTORICAL NARRATIVE AND DISCUSSION

The history of music, like that of any people or art, is not one of uninterrupted progress towards some ideal perfection. For five centuries or more music in the West has achieved peaks of accomplishment in one style or another before society has dictated or composers have felt the need for something new and different. Thus Wagner's music-drama *Parsifal*, lasting five hours, is not necessarily a more rewarding work than what Monteverdi achieved in *Orfeo* 250 years earlier. More complex yes, more rewarding—well, that is for the listener to judge.

We must keep this in mind when considering the development of music from a starting point of, say, early plainchant down to the complicated structures of a Schoenberg in our own day. In this development there is no true dividing line between one period and another, nor must simplifying terms such as "classical" or "romantic" be taken too literally.

Introduction.

In the recent past, general histories of music usually started from around 1600 with the implication that earlier music was primitive, and not worth serious consideration. This view has changed, largely as a result of the number of excellent performances and recordings available of medieval music by groups such as Gothic Voices, and the Hilliard Ensemble. These performances show that the music of the 14th and 15th centuries is just as complex and beautiful as anything written afterwards. There are clear parallels between the highly structured works of Machaut and Dufay, and the music of the mid to late 20th century.

Defining Medieval Music.

The term 'medieval' in music usually means the period from approximately AD 900–1500, beginning with the earliest examples of music notation, and ending with the transition to the Renaissance. In the medieval period, most performed music was monophonic (made up from a single line), improvised, and secular, probably with some form of drone. Most church music of the period was also monophonic, in the form of plainchant, with the more elaborate polyphonic settings of the mass reserved for special occasions.

Plainchant.

Plainchant is the fundamental basis of all Western music, and consists of a monodic song setting of the Christian liturgy in free rhythm. In monasteries today it is heard either with equal notes or a long-short rhythmic pattern, as there is no consensus. The pitches used are based on one of the 7 church modes such as the dorian (d, e, f, g, a, b, c, d). All medieval music is modal, the difference with tonal music being that there is much less of a pull to a key centre—it is less 'goal oriented'.

The Evolution of Organum.

In around 900 the first medieval treatise on music was written entitled *Musica Enchiriadis*. This contained some of the first examples of notated polyphonic music (music made up of more than one line), which is called *organum*. This genre evolved as an elaboration of plainchant, increasing the majesty of the liturgy. The first examples of what is termed '*florid organum*' occurred in the 12th century in Santiago de Compostela in Spain, and in St. Martial at Limoges in France. Florid organum consists of sustained notes of the plainchant, with florid quicker moving lines over this base. The technique evolved into a highly structured method of composition, which can be seen in the music of the 12th century Notre Dame School in Paris.

Leonin and Perotin.

The two names associated with this school are Leonin (*fl.* 1175) and Perotin (*fl.* 1183), although very little is known about their lives. Leonin composed a cycle of two part graduals, alleluias, and responsories for the church year called the *Magnus Liber Organi* (or great book of organi). Perotin expanded this work by composing new substitute sections called *clausulae*, which use the melismatic or florid part of a plainchant as its structural basis or tenor. There are usually 2 or 3 upper voices placed above the tenor, and all the parts move at the same pace. The term 'Tenor' is not the voice type, but the term for the main structural voice, usually the lowest.

The Motet.

The development of the clausula is significant because it creates a greater compositional freedom for the composers of the time, allowing them to display their artistry. The motet evolved from the clausula, and flourished in the 13th and 14th centuries. It consisted of the setting of a new text to an existing clausula, and the name came from the French for word: '*mot*'. With the development of the motet, the music became separated from the liturgy, and the words could now be based on love, and politics, as well as spiritual themes.

The Use of Isorhythm.

The main structural feature of the medieval motet is the use of isorhythm. This technique consists of a repeated rhythmic pattern, known as a talea, in the tenor, which is projected onto a repeating pattern of pitches, usually derived from a plainchant known as the color. The other parts created free polyphony around the slower moving tenor, using bare sounding perfect fifths and unisons as the basic harmonic consonance of the music.

The Notation of Rhythm.

The next main musical development in the later 13th century was in the notation of rhythm. Until Franco of Cologne's treatise of 1260 *Ars Cantus Mensurabilis* or 'Art of Measured Song', rhythms had been restricted to a small number of 'modal' patterns. Franco codified a new way of notation which allowed each note to have a number of different durations, creating far more rhythmic flexibility, and establishing the basis of a system that has not fundamentally changed upto the present day.

Ars Nova.

Philippe de Vitry (1291–1361), a French composer and theorist, built upon this in his treatise *Ars Nova* or 'New Technique/Craft' written in 1316, and also in his rhythmically complex motets. Once the term 'Ars Nova' gained currency as a description of the music of the 14th century, the previous period of the Notre Dame School, became described as 'Ars Antique', or 'Old Technique/Craft'. The music of the 14th century became much richer and more varied as a direct result of this innovation of notational practice.

Probably the most significant and versatile composer of this time was the Frenchman Guillaume de Machaut (1300–77). Machaut was a canon, a poet, and secretary to several kings, and his compositional output included secular chansons such as lais, ballades and rondeaux, as well as motets and the seminal *Notre Dame* Mass. The latter, probably a mature work, is very signicant because it was the first time a composer had written a complete mass cycle—a complete setting of the ordinary of the mass. It is an austere but very beautiful work and uses both isorhythmic and discant styles. Discant style is used for the longer texts such as the Gloria, and consists of one note per syllable of text. The isorhythmic movements such as the Kyrie are melismatic, and therefore they have many notes for each syllable.

The Cantus Firmus.

It was not until the following century that the composition of complete mass cycles became the norm. The main innovation in the composition of masses in the 15th century was probably first used in Britain, and is the use of a Cantus Firmus to unify the mass cycle. A Cantus Firmus is a pre-existing melody which is used as the structural basis of the mass, and is usually in the Tenor although it can be found in the other voices. The melody could be plainchant or a well known secular song, such as the French *L'Homme Armé*, which was particularly popular. Another significant shift is the development of more 'tonal' sounding harmonies and cadences.

The Work of Dunstable.

The British composer John Dunstable (1385–1453) was significant in the development of a more consonant and richer harmonic language on the mainland of Europe, particular the use of 3rds and 6ths. The evolution of style can be heard in the music of 15th century composers such as Guillaume Dufay (1400–74), and Josquin des Préz (1440–1521) which paved the way for the rich harmony and polyphony of the Renaissance. The medieval period showed an extraordinary evolution of style and technique, and produced music which is as beautiful and subtle as any work produced in later eras.

Josquin and his Successors.

Josquin des Prez was the outstanding composer of his generation, recognised as such by his contemporaries. His works combine technical mastery with imagination and attention to the text. The handling of the cantus firmus in his masses shows a variety of approaches, from the strict planning of the *Missa L'homme armé super voces musicales* to the freedom of his late masterpiece the *Missa Pange lingua*. His contemporaries include Isaac (*c.* 1450–1517) and de la Rue (*c.* 1460–1518), both of whom, like Josquin, explored the possibilities of canon as a structural basis for compositions. Josquin's music is noted for clarity and balance of texture and structure. Composers of the post-Josquin period, notably Willaert (*c.* 1490–1562), Gombert (*c.* 1500–56) and Clemens non Papa (*c.* 1510–58) developed instead a style pervaded by the technique of imitation, with full textures and a sense of seamless continuity.

An important advance in the early 16th cent. was the development of music printing, associated particularly with Petrucci in Venice and Attaignant in Paris; this made music much more widely available, and contributed to the spread of domestic music-making.

Reformation and Counter-Reformation.

The religious upheavals of the 16th and 17th cents. had their effect on music. Martin Luther was a keen musician, and allowed music a significant role in the liturgy of the new Lutheran churches; the chorale, or congregational hymn, sung in German, was the main new genre, to which Luther himself contributed many examples. A fine tradition of Lutheran church music developed over two centuries, represented by such composers as Praetorius, Schütz, Buxtehude and the Bach family. The more radical, Reformed Protestantism, however, under the leadership of Calvin in Geneva, gave music a much less important place, distrusting any kind of elaborate musical effects in worship. Organs were removed from churches and singing was restricted to metrical psalms. In England, the distinctive national church established under Elizabeth I—Protestant in doctrine, but Catholic in aspects of organisation and liturgy—provided plentiful opportunities for a strong musical culture; anthems and settings of the service attracted some of the most gifted musicians of the later Tudor and early Stuart period. The Catholic Counter-Reformation also turned its attention to music: the Council of Trent recommended a simplified musical style suitable for the clear enunciation of the text.

The Late Renaissance: Palestrina, Victoria, Lassus and Byrd.

The final flowering of Renaissance music is represented at its best by four composers. Palestrina (*c.* 1525–94), working for his whole career in or near Rome, is noted for the purity of his style, which for centuries to come would be taken as a model of "strict" counterpoint. Victoria (*c.* 1548–1611) studied in Rome, but spent his last three decades in his native Spain, where he continued the tradition of Spanish sacred music of Morales (*c.* 1500–53) and Guerrero (*c.* 1528–99). Victoria's output is notable for religious intensity and sensitivity to the text. Lassus (1532 94), Franco-Flemish by origin, spent virtually all his career in the Bavarian court at Munich, but was renowned throughout Europe. He produced a prodigious amount of sacred music with a wide expressive range from the exuberant to the penitential, and also composed many secular vocal works in French, German and Italian. In England, Byrd (*c.* 1540–1623) was a Catholic, but was so highly regarded by Elizabeth I that in 1575 she granted him and his colleague and co-religionist Tallis (*c.* 1505–85) an exclusive licence to print music. He was equally at home setting Latin texts and writing music for the new English liturgy; his music is full of expansive, rich polyphony infused with rhythmic life.

The Venetian Tradition.

Venice had a distinctive musical tradition, with music playing a major role in state occasions. Willaert, working at St. Mark's Basilica, established the polychoral style, in which music is shared between two (or more) choirs, spatially separated. This technique was extended by Andrea and Giovanni Gabrieli (uncle and nephew), incorporating solo voices and instruments in ever-varying textures—a fine example is Giovanni Gabrieli's *In ecclesiis*. Concerted instrumental music, especially for brass, was another important part of the Venetian repertoire.

Instrumental Music.

The 16th cent. saw instrumental (especially keyboard) music emerge as a significant genre in its own right. The Spaniard Cabezón (*c.* 1510–66) was a pioneer, and his example was followed by a whole group of English composers, notably Byrd, Bull, Gibbons and Farnaby; in turn, this English school had its influence on the Dutchman Sweelinck (1562–1621) and thereby, indirectly, on composers in Germany; Frescobaldi (1583–1643) was the outstanding figure in Italy. A variety of music was composed: pieces based on polyphonic vocal styles (ricercars, canzonas, fantasias); improvisatory types (preludes, toccatas); dances; and variations based on dances and popular songs.

The Madrigal.

The main form of secular vocal music in the Renaissance period was the madrigal, an Italian form (though some of its practitioners were Flemish). Whereas sacred vocal polyphony, even at its most expressive, tended to adhere to rules of harmony and part-writing, the passionate, thinly disguised eroticism of madrigal poetry led composers such as de Rore, de Wert, Marenzio, Monteverdi and Gesualdo to extremes of experimentation in which musical coherence and balance took second place to conveying every last detail of the text. The English madrigal, influenced by Italian models, in particular Marenzio, had a relatively short-lived life, flourishing in the work of composers such as Wilbye and Weelkes.

The Early Baroque and the Beginnings of Opera.

The name "Baroque" is commonly given to the period starting around 1600. Various elements came together at this time to change radically the direction of music. Emphasis on the solo voice (or instrument) with chordal accompaniment, and a sense of directed harmonic movement built upon the bass line, are crucial developments; equally significant is the new sense of drama, evident in all the arts of the period, and exemplified strikingly by the birth of opera. Towards the end of the 16th cent. a group of artistic intellectuals (the *Camerata*) met in Florence and conceived the idea of reviving the original performance style of Greek tragedy. They cast Greek mythological subjects in dramatic form and set them to music of a new declamatory type, recitative. The earliest examples were Péri's *Dafne* (1597), now lost, and his *Euridice* (1600).

Monteverdi's Operas.

It was *Orfeo* (1607) by Monteverdi (1567–1643) that showed the full potential of musical drama; it features not only highly expressive recitative, but arias, dances and madrigalesque choruses, and contains colourful instrumentation. Of Monteverdi's later stage works, his final opera, *L'Incoronazione di Poppea* (1642), is based not on mythology but on an episode in Roman history; it is remarkably "modern" in its focus on the psychology and emotions of its characters, unerringly delineated in musical terms. Monteverdi's successors were Cavalli (1602–76) and Cesti (1623–69), in whose works the distinction between aria and recitative became more fixed and there was increasing emphasis on vocal display.

Seventeenth-Century Sacred Music in Italy: Monteverdi and Carissimi.

New soloistic styles also affected sacred music, but without completely replacing the old polyphonic methods. Monteverdi's great *Vespers* of 1610 were a compendium of current choral, solo and instrumental techniques, and his later collections of sacred music were both varied and up-to-date. The main new genre of sacred music in the earlier 17th cent. was the oratorio, particularly cultivated in Rome by Carissimi (1605–74); his oratorios are sacred dramas—biblical stories (in Latin) set to music for soloists and chorus, but performed unstaged. *Jephte* is perhaps Carissimi's masterpiece, and it influenced Handel's own setting of the Jephtha story a century later.

German Music from Schütz to Buxtehude.

Italian influences came to Germany especially through the music of Heinrich Schütz (1585–1672), who studied with Giovanni Gabrieli in 1609–12; he visited Venice again in 1628–9, becoming acquainted with the latest developments pioneered by Monteverdi. He composed the first German opera, *Daphne* (1627), now lost; apart from this and a set of Italian madrigals, his output consists of sacred music for the Lutheran church. Schütz's ablity to match his music to the text, and his dramatic and pictorial sense, are remarkable, whether in the spacious polychoral writing of the *Psalmen Davids*, the atmospheric depiction of St. Paul's conversion (in *Saul, Saul*), the colourful instrumentation of the *Christmas Story*, or the austere Passion settings (Matthew, Luke and John). Johann Herman Schein (1586–1630) is also a significant figure in church music; unlike Schütz, he made considerable use of Lutheran chorales. Samuel Scheidt (1587-1654) is important chiefly for his instrumental music.

The Danish-born Dietrich Buxtehude (1637-1707) was the outstanding figure in North German music of his generation. His church cantatas and organ music influenced J. S. Bach. The devotional spirit in the Catholic South is represented by Heinrich Biber (1644–1704), whose "Mystery" (or "Rosary") Sonatas for violin (of which he was a virtuoso exponent) are notable for their experimental use of *scordatura* (non-standard tunings of the strings).

Seventeenth-Century Music in France and England.

French opera was from the beginning associated with the court ballet. The Italian-born Jean-Baptiste Lully (*c.* 1632–87) created the characteristic form of the *tragédie lyrique*, which dominated the French musical stage until the mid-18th cent. In Lully's operas the libretto plays a vital role, the text being set in a flexible, naturalistic way, with a less clear distinction between recitative and aria than in Italian opera. The orchestration, chorus and dances assume greater importance than in the contemporary Italian form. In his lifetime, Lully's musical monopoly under Louis XIV limited the outlets for other opera composers. An outstanding opera composed and performed after Lully's death is *Médée* (1693) by Marc-Antoine Charpentier (1643–1704). Charpentier is best known, however, for his church music, of which the *Te Deum* (*c.* 1691) is a colourful example.

In the instrumental field, the lute music of Denis Gaultier (1603–72) stimulated the development of an idiomatic harpsichord style in the dance suites of J.C. de Chambonnières (1602–72), Louis Couperin (1626–61) and J.-H. d'Anglebert (1635–91).

In England, opera developed from the Masque, an entertainment consisting of dances, songs and poetry, with elaborate stage effects, often incorporated into a drama. Examples are Henry Lawes's (1596–1662) setting of Milton's *Comus* (1634), and *Cupid and Death* (1653) by Matthew Locke (1622–77) and Christophper Gibbons (1615–76). John Blow's (1649–1708) *Venus and Adonis* (*c.* 1684) is called a masque but is in effect an opera, with the whole text being sung.

Henry Purcell.

It was Henry Purcell (1659-95), Blow's pupil, who in *Dido and Aeneas* really exploited the new medium by his power of subtle musical characterisation. Dido's lament "When I am laid in earth" uses typically bold harmonic effects to achieve a remarkable expressive power. These works by Blow and Purcell, however, are exceptions. The favoured form was the semi-opera - essentially a play with a substantial amount of music - to which Purcell contributed some fine examples, such as *The Fairy Queen* (1692).

Purcell's sacred music is also of a high order, representing the culmination of the Restoration style forged from earlier English and newly fashionable Italian and French influences by such composers as Matthew Locke and Pelham Humfrey (1647–74). Purcell's instrumental music includes work in older genres (the Fantasias for viols, which are imaginative, even eccentric, in their approach to harmony and counterpoint); he also adopted the new Italian violinistic style in his Sonatas of Three and Four Parts.

The Concerto Grosso.

The idea of groups of instruments set off against each other goes back to the early 17th cent. (*e.g.* Giovanni Gabrieli's *Sonata pian'e forte*). With Arcangelo Corelli (1653–1713) the concerto grosso took a more definite shape, alternating a solo group of instruments with the main body of strings in three or more contrasting movements. Guiseppe Torelli (1658–1709), Francesco Geminiani (1687–1762) and Tommaso Albinoni (1671–1750) were other notable contributors to the form, but none of the composers so far mentioned has today achieved the popularity of the priest Antonio Vivaldi (*c.* 1678 1741), himself a violinist, who had at his disposal the orchestra at the Ospedale della Pieta in Venice. The young women at this music school also contributed the vocal side of the concerts there of which there are many descriptions. One says: "They sing like angels, play the violin, flute, organ, oboe, cello, bassoon—in short no instrument is large enough to frighten them . . . I swear nothing is so charming than to see a young and pretty nun, dressed in white, a sprig of pomegranate blossom behind one ear, leading the orchestra, and beating time with all the grace and precision imaginable." For this body, Vivaldi wrote about 500 concertos which maintain a remarkably even quality, but "The Four Seasons" are perhaps the most felicitous.

Chamber Music.

In the field of chamber music the trio sonata became the predominant genre by the late 17th cent., and again Corelli was a major figure in its evolution. Trio sonatas were composed for two treble instruments (most commonly violins) and continuo, and fell into two main types: the *Sonata da chiesa* (Church sonata, generally with a slow-fast-slow-fast pattern of movements), and the *Sonata da camera* (Chamber sonata, a dance suite).

Meanwhile the tradition of French harpsichord music culminated in the work of Jean-Philippe Rameau (1683-1764) and François Couperin (1668-1733). Masters of keyboard style and harmonic invention, they wrote many pieces of subtle charm and exquisite craftsmanship, often with descriptive, and sometimes enigmatic, titles.

Bach and Handel.

The contrasting figures of J. S. Bach (1685 – 1750) and Handel (1685 – 1759) dominate the first half of the 18th cent. Bach was essentially a provincial musician, from an extended family of musicians, working for the court (at Weimar, 1708-17, and Anhalt-Cöthen, 1717-23) and the Lutheran church (in Leipzig from 1723). Handel, on the other hand, was widely travelled beyond his native Germany, spending some time in Italy before settling in England and eventually becoming a naturalised English subject; although he had noble patrons and composed music for state occasions (notably the four anthems for the coronation of George II), he was mainly a freelance composer – indeed a businessman – writing for and dependent upon the public. Both composers, however, show an extraordinary breadth of achievement, expressive range and depth, and strong musical personalities.

The Music of Bach.

Bach composed in all the main genres of his time except opera. He absorbed and transcended the "national" styles (Italian, French, German) of his day. As a master of contrapuntal writing he was second to none, but he rose above technical brilliance to achieve intense emotional and expressive power. He systematically explored the possibilities of musical forms (in *e.g.* the *Well-tempered Clavier* – generally known as the "48" – two sets of preludes and fugues in all the major and minor keys), structural devices (*e.g.* both variation and canon in the "Goldberg" Variations for harpsichord and the late canonic variations for organ on the chorale *Von Himmel Hoch*) and themes (in the *Musical Offering* and *Art of Fugue*, his last, incomplete work).

Central to Bach's achievement is his Lutheran church music – notably the more than two hundred cantatas (mostly from his Leipzig years, but some composed in Weimar) and the St. John (1724) and St. Matthew Passions (1729). The Passions combine highly dramatic setting of the New Testament story of Christ's death with expressive commentary; soloists and choir take part in the narrative (as the various characters, the crowd *etc.*) and reflect on it in extended and often elaborate arias and choruses, while the inclusion of chorales (Lutheran hymns), as in the cantatas, enables the congregation itself to participate. In contrast to these works intended for use in the church service, is the so-called B minor Mass (the title is not Bach's), a large-scale setting of the Roman Catholic Mass, which Bach compiled in the 1740s, mainly adapting music from his earlier compositions. This hugely impressive work could hardly have been meant for performance in Lutheran Leipzig; perhaps Bach put it together for his own satisfaction.

Bach made important contributions to the various instrumental forms of his time, both solo and concerted. His organ music – preludes and fugues, chorale preludes, trio sonatas – is central to the repertoire of the instrument. The sonatas and partitas for unaccompanied violin and suites for unaccompanied cello combine meditative depth and rhythmic life. The violin concertos build upon the three-movement model developed by Vivaldi, while the six Brandenburg Concertos, each for a different combination of instruments, are a culmination of the tradition of the concerto grosso.

Handel's Operas.

The first part of Handel's career in London, from 1711, was dominated by the composition of Italian operas, the second part from the late 1730s, by oratorios. While the latter have never fallen out of favour, the former were largely neglected for more than two centuries (except for occasional arias which remained popular as recital pieces or in various adaptations – most famously "Ombra mai fù" from *Serse*, better known as "Handel's Largo"). The tradition within which Handel was composing, with its succession of recitatives and arias, provided little opportunity in musical terms for dramatic development or interaction between the characters; by comparison with Mozartian opera, or with many operas of the 19th and 20th cents., the form is static, and it could easily become little more than a vehicle for vocal display. Handel's masterpieces in the genre, however, are much more than this, and reassessment of his operas in recent decades has led to a renewed appreciation of their musical qualities – memorable melody, daring harmony, imaginative instrumentation – and of the vivid characterisation they contain. Most important, the modern productions have shown that they can be made to work in the theatre, and a number of them are now regularly found in the repertoire of opera-houses.

Handel's Oratorios.

As the vogue for Italian opera waned Handel turned to oratorio as a new form of large-scale vocal music for public consumption – indeed, he virtually invented the English oratorio. Operatic in conception, the Handelian oratorio is an unstaged musical drama on a biblical subject (usually from the Old Testament), with a libretto in English. Crucial is the important role of the chorus, taking part in and commenting on the action (whereas choruses feature scarcely at all in Handel's Italian operas.) The great sequence of Handel's oratorios started with *Saul* in 1738, running through to *Jephtha* in 1751. Handel's most popular oratorio *Messiah* (1741), is an exception to the general type being based around the figure of Christ and using exclusively biblical words. Handel's dramatic and pictorial sense and his ability to create striking effects are demonstrated time and again in his oratorios.

In his instrumental and orchestral works Handel was less systematic in approach than Bach; for example, his keyboard suites vary considerably in their format, unlike the suites and partitas of Bach with their regular, standard succession of dance movements. The Concerti Grossi Op.3 and Op.6 show a colourful use of instrumental resources, as do occasional works such as the *Water Music* and the *Royal Fireworks Music*. The organ concertos call for some virtuosity; Handel would often play them between the acts of his oratorios.

Developing New Styles.

Even while Bach and Handel were creating the corwning achievements of baroque polyphony, new styles were emerging which were eventually to result in the high classical style of the later 18th cent. Among the contributing features were: a preference for accompaniment rather than polyphonic textures; relative simplicity of harmony; symmetry and regularity of phrase structure; and a general elegance of style. These tendencies can be found in the earlier part of the 18th cent. in *e.g.* the keyboard sonatas of Domencio Scarlatti (1685-1737), in the Italian opera overture (or *sinfonia*, the foundation of the classical symphony), and in comic opera, *e.g. La serva padrona* by Pergolesi (1710-36), and continued through the middle years of the century. One of the most important later representatives of this "gallant" or "rococo" manner was J.C. Bach (1735-82), whose sonata and concertos had a strong influence on Mozart.

Music in the "pre-classical" period was, however, by no means always light-hearted or simple. Intensity of expression by means of minor keys, chromatic harmony, urgent, incisive rhythm and dramatic contrast is found in *e.g.* some of the keyboard music of the 1740s and later of C.P.E Bach (1714-88); the term *empfindsamer Stil* ("expressive style") is often applied to this music. Various works of the late 1760s and early 1770s, notably some of Haydn's symphonies (*e.g.* No.49 in F minor, ìLa Passioneî of 1768) display similar emotionalism, and have been compared with the contemporary *Sturm und Drang* ("Storm and stress") movement in literature. Aspects of this more serious approach were absorbed into the emerging classical style.

The invention and rapid development of the fortepiano from the 1730s was to have far-reaching consequences. With its capacity for a range of dynamics it eventually replaced the harpsichord and clavichord as the preferred stringed key board instrument for public and domestic music-making. The beginnings of the modern orchestra also date from this period; the court of Mannheim's orchestra was of a standard unheard hitherto, and the Mannheim composers, notably Johann Stamitz (1717-57), played an important part in the development of the symphony, although this is overshadowed by the achievements of Haydn in the service of Prince Esterházy.

Haydn and Mozart.

These two figures dominate the second half of the 18th cent. as Bach and Handel do the first. In a brief space only a general picture can be presented of their huge output and influence. Of Haydn's 104 symphonies (there may even be others) nearly all are worthy of study and hearing. The craftsmanship is always remarkable, the invention ever new. Indeed without Haydn's harmonic daring or his melodic ingenuity, the even greater symphonic thought of Beethoven would have been impossible: Haydn laid the groundwork on which his successor built towering edifices. A work such as the 93rd symphony in D is typical of his mature style with its searching introduction, powerfully wrought, earnestly argued first movement, beautiful *Largo* and resourceful bustling finale. Haydn did not fight shy of contrapuntal writing: the development section of this symphony's first movement and the finale are evidence of that, but it was only as an integral part of a predominantly homophonic technique.

Mozart's symphonies are not so different in form from Haydn's but—and this must be a subjective judgment—he put more emotional feeling into his. Nobody could listen to the heart-searching first movement of his 40th symphony without being deeply moved. It was in his final three works in the medium that Mozart brought his symphonic art to perfection, and these obviously had an effect on Haydn's later symphonies written after them. For passion and tenderness contained within a classical form these late symphonies, and many other of Mozart's works, have yet to be surpassed.

Haydn, who has been rightly termed "the Father of the Symphony", was also the founder of the string quartet—perhaps the most perfect, because the most exactly balanced, form of musical expression. The four instruments—two violins, viola, and cello—discuss, argue, commune with each other over the whole gamut of feeling. In his quartets Haydn's mastery of structure is even more amazing than in his symphonies. Mozart's quartets (especially the six devoted to Haydn) and even more his quintets achieve miracles of beauty in sound, nowhere more so than in the first movement of the G minor (his most personal key) quintet. The two late piano quartets show how the piano *can* be combined with strings. His clarinet quintet is also a masterly work.

Mozart's Concertos.

Haydn did not leave any concertos of consequence. Mozart's, especially those for piano, are among his greatest works. As a brilliant clavier player himself, he showed a consummate skill in writing for the keyboard. Although the instrument he knew was slightly less advanced than the piano today, his concertos call for virtuosity in execution, yet they are as searching in emotional content as the late symphonies and quartets. Indeed the C major concerto (K. 467) and the C minor (K. 491) may be said to hold the quintessential Mozart. As well as twenty (mature) piano concertos, Mozart wrote six for the violin, four for the horn, and eighteen others, but none of these can be placed in quite the same class.

Of their church music, Haydn's sixteen masses and his oratorios—*The Creation* and *The Seasons* (both late works)—are perhaps more worthy of attention than Mozart's various masses, but we must not forget Mozart's final work—the Requiem or the serene late Motet *Ave Verum Corpus*.

Eighteenth-Century Opera.

Mozart—for many the first great opera composer—did not, of course, create his masterpieces out of nothing. In France, Lully was followed by Rameau (1683–1764), who carried on his tradition of using classical themes but developed a more flexible style of recitative and greatly increased vividness of expression. But it was Gluck (1714–87) who more than anyone broke out of the straitjacket of the now ossified Italian form of opera—dominated by the singer—and showed just what could be achieved in moving human terms.

Drama in music really came of age with his *Orfeo e Euridice* (1762), *Alceste* (1767) and *Iphigénie en Tauride* (1779). His simplicity and poignancy of expression were not lost on Mozart.

Meanwhile in Germany a kind of opera called *Singspiel* appeared during the 18th cent. Breaking away from classical themes, mundane stories were told in dialogue and music.

Until quite recently Haydn's operas were dismissed as unworthy representations of his genius but, chiefly through the enlightening efforts of the Haydn scholar, H. C. Robbins Landon, some of his fifteen surviving works in the medium have been successfully revived. They have proved to be perfectly viable for the stage and, especially in the ensembles, full of that delightful invention to be found in the rest of his opus, if on a less fully developed scale. Still as musical drama they inevitably fall far short of Mozart's achievements, for the younger composer seems to have had an instinctive feeling for the stage. Into his operas he poured his most intense, personal music. He vividly portrays the foibles, desires, loves, and aspirations of mankind.

The earlier, immature stage pieces of his youth led to such works as *Lucio Silla* (1772) and *La Finta Giardiniera* (1775) with their first glimpses of the glories to come. His first indubitably great opera is *Idomeneo* (1781). Despite its unpromisingly static plot, *Idomeneo* reveals Mozart's stature through its ability to breathe new life into a conventional *opera seria* form. Though influenced by Gluck it is yet more human and touching in its musical expression. To succeed this Mozart wrote a much more frivolous piece *Die Entführung aus dem Serail*. Stemming from the *Singspiel* tradition, it none the less creates real-life characters who have much charming music to sing.

Mozart's Masterpieces.

After three lesser pieces Mozart embarked on his four masterpieces—*Le Nozze di Figaro* (1786), *Don Giovanni* (1787), *Così fan tutte* (1790), and *Die Zauberflote* (1791).

Figaro, as well as being a delightful comedy, explores more fully than any previous opera situation and character, which find expression in beautiful arias and in two finales of symphonic proportion. In *Don Giovanni*, less satisfactory as a dramatic structure, the range of musical characterisation and insight into human motives is widened still further. *Così* lyrically but humorously expresses the follies of love. Mozart could not help but love his characters and his music for them is at one and the same time amusing and heartfelt, *Die Zauberflöte*—The Magic Flute—displays Mozart's deep-felt concern for his fellow men and for truth in an opera of great spiritual strength. Nor has opera any more loveable personality than the birdcatcher Papageno. Mozart's final opera *La Clemenza di Tito*, extolling imperial magnanimity, has never achieved the success or popularity of his other maturer stage works, though it contains much excellent music, and has recently been revived with honour in several opera houses.

Beethoven.

Mozart was the last major composer to depend, to any large extent, on private patronage for his living, and even he left the service of the Archbishop of Salzburg because he could not stand the restrictions imposed on his freedom. Henceforth composers would have to stand on their own two feet with all the advantages (liberty) and disadvantages (lack of security) that implied. Beethoven (1770–1827) was the first such composer of importance.

Although his work is usually divided into three periods, that division is somewhat too arbitrary, for no other composer in history, with the possible exception of Wagner, has shown such a continual development of his genius. Coming at just the right moment in musical history, he crowned the achievements of Haydn and Mozart with music of the utmost profundity of thought and feeling that looks back to its classical heritage and forward to the romantic movement of the 19th cent. His influence on musical thinking and writing is incalculable.

His first period shows his strong melodic gifts and the beginning of his individuality in developing form and structure to suit his own ends and match his particular genius. Unusual keys are explored, unusual harmonic procedures employed.

With the "Eroica" (his third symphony) he established his position as a great composer. The unity of purpose he here achieved within a long and diverse structure is truly staggering, even today. In the first movement alone the formal invention and cogency went far beyond what even Mozart had achieved in his "Jupiter" symphony, and the second movement—a vast funeral March—has an overwhelmingly tragic emotional content. But the "Eroica" was followed by six equally great symphonies, each one as varied, as inventive, as unified as the others. The ninth symphony is significant both for its length and its finale. Here Beethoven crowns three superb instrumental movements with a choral movement that, as well as summing up all that has gone before, expresses in music the joy in existence more ecstatically than any other work.

The burning intensity of Beethoven's genius is just as evident in his chamber music. His quartets are the product of a revolutionary age in which the social graces and formal restraint of the 18th cent. were thrown off in a search for a more personal mode of expression. The early op. 18 set, and the Razoumovsky quartets, op. 59, go even beyond the range of Haydn's and Mozart's works in the medium but it was in his late quartets, his final musical testament, that Beethoven refined and distilled his art for posterity. No words can possibly describe their unique quality, but any and every chance should be taken to make their acquaintance; the effort required will be more than amply rewarded.

The early piano concertos do not reach quite that level of attainment, but the last three, together with the violin concerto, are on a par with the finest of the symphonies and quartets, as well as being considerable tests of the performers' technique. The Triple Concerto for piano, violin, and cello is an unusual and rewarding work.

His Choral Work.

Beethoven's grandest choral work—and one of the most noble in existence—is the Mass in D (*Missa Solemnis*). Its vast scale and sublime utterance often defeat performers, but when it is successfully done there is no more spiritually uplifting experience for the listener, except perhaps Beethoven's only opera, *Fidelio*. This simple escape story was transformed by Beethoven's creative fire into a universal symbol of liberty, the composer identifying himself with the struggle for freedom from tyranny and release from darkness.

Beethoven lived in a period of war and revolution. A passionate believer in the brotherhood of man and in liberty, he was shocked to find his ideals thrown over by revolutionaries-turned-dictators. His own tragedy of deafness, which came upon him at the moment of his triumph, nearly submerged him, but in the end he won through and produced the string of masterpieces from the "Eroica" onwards. Hope springing from despair, love from hatred, victory over defeat, these are the unquenchable legacies left by Beethoven.

The Romantic Movement.

Inevitably, the Romantic movement in literature that burst forth about 1800 was bound to have its counterpart in music. And so it was. Breaking the classical bonds, composers such as Schubert, Schumann, Liszt, and Berlioz sought a new freedom in musical expression. Form became of less importance than content; and that content often had literary connections. For their purposes a larger orchestra was needed and supplied, but the miniature, the song especially, because of its very personal connotation, was also a favourite form.

Schubert.

Schubert (1797–1828)—described by Liszt as "the most poetic of musicians"—is perhaps the greatest lyrical genius in musical history. In him the Viennese tradition and influence of Haydn, Mozart, and Beethoven reached its zenith. The song was always Schubert's starting point, so it is hardly surprising that his reputation as a song writer has never been impaired but in his symphonic and instrumental works too it is always his inexhaustible fund of melody that first calls for attention. Nobody could listen to his "Trout" quintet, for piano and strings, his octet, his fifth symphony, or his song cycle *Die Schöne Müllerin* without being enchanted and invigorated by the sheer tunefulness of the music. But there is much more to Schubert than this: his understanding of the possibilities of harmonic change, his grasp of orchestral coloration (in the great C major symphony, for instance), his free use of sonata structure.

Although Mozart, Haydn, and Beethoven had all contributed to the song as an art form, it was with Schubert that it achieved its first full flowering. If he had written nothing but his songs, his place in the musical firmament would be assured. With his *Erlkönig* in 1815 the German *Lied* came of age and from then until the end of his life he wrote more than six hundred songs, hardly a dud among them. Whether it is the charm of *Heidenröslein*, the drama of *Der Doppelgänger* or the numbed intensity of the *Winterreise* cycle, Schubert unerringly went to the heart of a poet's meaning; indeed he often raised poor verses to an inspired level by his settings.

There is only room to mention one or two other composers, some of them wrongly neglected, who were roughly contemporaries of Beethoven and Schubert: the Czech Dussek (1760–1812), who like Beethoven bridges the classical–romantic gulf, Boccherini (1743–1805), the two Italian opera composers Cimarosa (1749 1801) and Paisiello (1740–1816), the Frenchman Méhul (1763–1817) and the German Hummel (1778–1837).

Weber (1786–1826) lacked Beethoven's energy and constructive powers and Schubert's sheer lyrical profundity, but he is an important figure, especially in the field of opera, where his *Der Freischütz* and *Oberon* led the way to a more flexible, dramatically realistic form of opera. His vivid imagination exactly fitted the new romantic mood abroad. The sheer beauty in the melodic shape of his music is undeniable. His instrumental works are attractive but insubstantial.

Mendelssohn.

Mendelssohn (1809–47) was the civilised craftsman among the Romantic composers. A boy genius—many of his finest works were written before he was twenty—he maintained the importance of classical form while imbuing it with his own affectionate brand of poetic sensibility.

His third and fourth symphonies—the "Scottish" and "The Italian"—(and possibly the fifth "The Reformation"), his string quartets (some of which go deeper than the rest of his music), octet, violin concerto, first piano concerto, and of course, the incidental music to "A Midsummer Night's Dream" represent his tidy yet effervescent style at its most winning.

Schumann.

Schumann (1810 56) is less easy to categorise. His early romantic flame was burnt out by some flaw in his intellectual and/or emotional make-up, and his inspiration seems to have declined in later years. No matter, by then he had given us the marvellous song cycles of 1840, an ever fresh piano concerto, many fine piano solos, including the mercurial, popular *Carnaval* and four symphonies, which, if not structurally perfect, contain much lovely music.

The joys and sorrows of love and the feeling for natural beauty are all mirrored in these charming, lyrical works, and in the piano quintet.

Berlioz.

Berlioz (1803–69) and Liszt (1811–86) are the two most typical representative composers of the Romantic era. Both have always been controversial figures, with ardent advocates and opponents either unduly enthusiastic or unfairly derogatory. Berlioz might be termed the perfect painter in music. With an uncanny mastery of orchestral sound he could conjure up the countryside, the supernatural and the historical with the utmost ease. He based his music on the "direct reaction to feeling" and a desire to illustrate literature by musical means. That his technical expertise was not always the equal of his undoubted genius, can be heard in many of his larger works such as the dramatic cantata *The Damnation of Faust* and the dramatic symphony *Romeo and Juliet*, yet most people are willing to overlook the occasional vulgarity for the ineffable beauty of his many fine pages, but brutal cuts in his music, such as are often made in, for instance, his epic opera *The Trojans* only have the effect of reducing the stature of his works. We must accept him, warts and all. Anyone who has seen the two parts of *The Trojans*, presented complete in one evening at Covent Garden, will realise that Berlioz knew what he was about.

His output is not quantitatively large but includes several monumental works, as well as *The Trojans*, The *Requiem* ("Grand Messe des Morts") requires a tenor solo, huge chorus and orchestra, and brass bands, although Berlioz uses these forces fastidiously. The *Symphonie funèbre et triomphale* calls in its original form, for choir brass, and strings. But Berlioz was just as happy writing on a smaller scale as his exquisite song cycle, to words of Théophile Gautier, *Nuits d'Eté*, shows. Gautier perhaps summed up better than anyone Berlioz's singular talent: "In that renaissance of the 1830s Berlioz represents the romantic musical idea, the breaking up of old moulds, the substitution of new forms for unvaried square rhythms, a complex and competent richness of orchestration, truth of local colour, unexpected effects in sound, tumultuous and Shakespearian depth of passion, amorous or melancholy dreaminess, longings and questionings of the soul, infinite and mysterious sentiments not to be rendered in words, and that something more than all which escapes language but may be divined in music."

Liszt.

During his lifetime Liszt was fêted and honoured not only by his musical colleagues but by the world at large, which idolised him and his piano. Then his reputation took a plunge from which it has only recently recovered. To be sure much of his early music is glitter and gloss, but his symphonies and tone poems—especially the Faust Symphony, the Dante Symphony (both, of course, inspired by literature), and *Orpheus* and *Prometheus*—and his late piano works show that he was an extraordinary harmonic innovator. The piano sonata in B minor brings his romantic, wilful temperament within a reasonably stable, pianistic form, and as such is a landmark in the repertory of the instrument. Liszt's output was prodigious, but the inquiring listener should explore the more original of his compositions already mentioned to appreciate his fertile genius.

Chopin.

Chopin (1810–49) was the master of the keyboard, par excellence. His development of the technical and expressive capabilities of the piano is unique in musical history. His inventive powers were poured out with nervous passionate energy and in a highly individual style through twenty astonishing, possibly agonised years of creative activity before his early death. A Chopin melody, limpid, transparent, singing, can be recognised easily by anyone, but his style gradually developed into something more subtle, more satisfying than pure melody. He took the greatest care of every detail so that any alteration, however small, upsets the perfect balance of his work. His poetic sensibility can be found in any of his works; for his constructive ability we must turn to the Ballades, the B minor Sonata, and the Barcarolle, while the Preludes and Studies blend technical powers and emotional expressiveness in ideal proportions.

Nineteenth-Century Opera.

After Mozart's operas and Beethoven's *Fidelio* the medium might have been expected to decline. Instead it took on a new, if different, lease of life that culminated in Verdi's extraordinary output.

Rossini (1792–1868) created a world of exuberant high spirits in his operatic works that are as cheerful and heart-warming today as they were when they were first performed.

He always worked in and around the lyric theatres of Italy and between 1810 and 1830 poured out a stream of works, not all of which can be expected to be masterpieces. However, *Il Barbiere di Siviglia*, *L'Italiana in Algieri*, *La Cenerentola* and *Le Comte Ory* will always delight audiences as long as opera houses exist. Although these works are difficult to sing really well, their vitality and charm can never be submerged even by poor voices or indifferent staging.

His German contemporaries were critical of his confidence and frivolity, but his works show a consistency of invention and an irresistible tunefulness that anyone might envy. In recent years, there has also been a renewed interest in his more serious operas—*Otello* (1816), *La Gazza Ladra* (1817), *Semiramide* (1823), *La Siège de Corinthe* (1820), and *Guillaume Tell* (1829)—which were certainly surpassed in dramatic power by his successors but which nevertheless are not to be despised or neglected.

William Tell, to give it its most popular title, was his last work for the stage although he lived on for nearly forty years in retirement in Paris, scene of many of his greatest successes. There he enjoyed good living, dispensing *bons mots*, and occasionally composing trifles. An exception is the unpretentious *Petite Messe Solennelle*, written originally for soloists, chorus, a harmonium, and two pianos. Rossini later orchestrated it, but he would not allow it to be performed during his lifetime. The first public performance was on 28 February 1869, as near as possible to the 78th anniversary of the composer's birth on Leap Year Day 1792.

Bellini.

In contrast to the mercurial Rossini, Vincenzo Bellini (1801–85) was an exquisite, romantic figure dealing with exquisite, romantic stories, an operatic equivalent to Chopin, who much admired him. His delicate, sinuous vocal line (in the arias) and brilliant acrobatics in the final sections (cabalettas) require singers of the utmost accomplishment to do them justice, although his music is never as florid as Rossini's. His most typical and popular works are probably *La Sonnambula* (1831), *Norma* (1831) and *I Puritani* (1835). The first is a tender, homely country story, the second an almost heroic lyrical drama of sacrifice, and the third a rather unsatisfactory historical story redeemed by its appealing music.

Donizetti.

Gaetano Donizetti (1797–1848) was an even more prolific operatic composer than Rossini. He wrote at least 75 works, mostly for the Italian stage, several of which, such as *Alfredo il Grande* or *Emilia di Liverpool*, are never likely to be revived, but during the past few years, with the renewed interest in what are called the *Ottocento* operas, many of his serious operas have been resuscitated and found as enjoyable in performance as his more frequently heard comedies.

He was a well-grounded musician and although his invention is often criticised for being too tied to the conventions of his day performances often belie this reputation, his dramatic instinct proving sure. *Lucia di Lammermoor*, because of the chances it offers to a coloratura soprano with tragic pretensions, has always held the stage and of late, *Lucrezia Borgia*, *Anna Bolena*, *La Favorita*, and *Poliuto* have all been successfully revived. Of his lighter works, the comedies *L'Elizir d'Amore* and *Don Pasquale* have never declined in popularity. One of his last works was *Linda di Chamounix* (1842) which he wrote for Vienna where it aroused such enthusiasm that the Emperor appointed him Court Composer and Master of the Imperial Chapel.

French Opera.

The taste in Paris was for more and more lavish productions. Following Spontini (1774–1851), whose works were comparatively austere, came Halévy (1799–1862) and Giacomo Meyerbeer (1791 1864) whose operas contain all the ingredients that came to be expected of "Grand Opera"—spectacle, huge ensembles, showpieces for the soloists, and extended, if superfluous ballet. Drawing from Italian, German, and French traditions Meyerbeer's works contained everything the public wanted, yet today they are seldom revived, perhaps because his creative powers were essentially derivative, yet when they *are* given, operas like *Les Huguenots*, *Le Prophète*, and *L'Africaine* still have the power to fascinate and his influence on his successors, notably Wagner, was considerable.

Verdi.

Italian opera in the 19th cent. culminated in the works of Giuseppe Verdi (1813–1901), who rose from a peasant background to become his country's most noted composer, as well as something of a natural hero during the period of the Risorgimento. His earliest works, indeed, often roused his hearers to patriotic fervour. For instance, *Nabucco* (1841), with its theme of an oppressed people seeking deliverance, was treated as a symbol of the Italians' fight for freedom.

Musically, Verdi developed out of all recognition during the course of his long career. The continuously flowing structure of his last two operas *Otello* and *Falstaff* is very far removed from the start–stop formulas, inherited from his predecessors, of his first works, yet even they are touched, in harmonic subtleties, orchestral felicities, and a sense of drama, by a spark of genius, a burning inspiration that sets him apart from all other operatic composers. *Ernani* (1844), *I due Foscari* (1844), and *Luisa Miller* (1849) all have foretastes of glories to come even if as a whole they are flawed dramas, and these "galley years", as Verdi himself later described them, gave him the essential know-how to produce his later, greater operas, as well as establishing him incontrovertibly as the most popular Italian composer of the time.

Verdi's Masterpieces.

However, it was with *Rigoletto* (1851), *Il Trovatore* (1853), and *La Traviata* (1853) that Verdi first really staked his claim to immortality. In these pieces his increasing dramatic mastery is married to a wonderful flow of lyrical melody, at the same time controlled by a fine musical sensibility. They were followed by four operas—*Simon Boccanegra* (1857), *Un Ballo in Maschera* (1858), *La Forza del Destino* (1862), and *Macbeth* (revised version, 1865)—in which Verdi overcame complexities of story line by his continually developing musical powers. This period is crowned by *Don Carlos* (written for the Paris Opéra, 1867) a masterly exercise in combining private and public situations in a single, grand, and characterful work. In some respects Verdi never surpassed the subtlety of his writing in this opera. *Aïda* (1871) carried on the process but the characterisation in this ever-popular piece is less refined than in *Don Carlos*, if the grandeur of the design is more spectacular.

The success of *Otello* (1887) owes nearly as much to the skill of Boito whose literary ability combined with musical knowledge (he was himself a composer) presented Verdi with an ideal libretto for his seamless music in which the drama moves inevitably to its tragic end. Recitative, aria, ensemble are fused in a single, swiftly moving music-drama, which in its very different way equals that of Wagner. *Falstaff* (1893) achieves the same success in the field of comic opera, a brilliant, mercurial ending to a distinguished career.

If Verdi had written only these two final masterpieces his place in musical history would still have been assured.

Brahms.

Brahms (1833–97) has justly been described as "a romantic spirit controlled by a classical intellect," for while complying with most of the formal regulations of sonata form he imbued them with an emotional content that accorded with his time. Indeed Schumann declared that he was the "one man who would be singled out to make articulate in an ideal way the highest expression of our time."

Perhaps in his chamber music will be found the quintessence of his art. The piano and clarinet quintets, the two string sextets, the horn trio, and the violin sonatas all are designed on a large scale yet the expression remains intimate, the design and structure clear.

The symphonies and concertos, though, remain his most popular works; they are part of the solid repertory of every orchestra and most piano and violin players in the world. Their high seriousness, constant lyrical beauty, and control of form are deeply satisfying. They do not provide the extremes of passion and excitement provided by his contemporaries, but their study provides continuous absorption and delight. The double concerto for violin and cello deserves a mention as a unique work in music.

Brahms wrote more than two hundred songs in which the desire for melodic beauty takes precedence over the words and meaning. Many are set to poor poetry, but hidden away are still some unexplored treasures, and the Four Serious Songs, at least, are tragic masterpieces. In a lighter vein the two sets of *Liebeslieder Walzer* for four voices are irresistible. The choral Requiem, too, is a fine work.

Bruckner.

In recent years Bruckner's reputation *vis-à-vis* his great contemporary Brahms has been enhanced in England. The old conception of him as a naïve Austrian unable to grasp the fundamentals of symphonic architecture has died hard, and the prevailing popularity of his grandest works is at last gaining him his rightful place in the 19th-cent. firmament. The nine symphonies and the masses are his chief claim to immortality. They contain melodies of unforgettable beauty, symphonic paragraphs of unparalleled grandeur, and an appreciation of formal development that, though different, is equally as valid as that of Brahms.

The movements of his symphonies are long and he often pauses, as if for breath and to admire the scenery, before he reaches the climactic peak of his musical journey. His idiom is best approached by a newcomer to his work through the fourth and seventh symphonies as they are perhaps the easiest to understand, but the fifth, sixth, eighth, and ninth (unfinished) are just as beautiful—and cogently argued—once one has acquired the knack, so to speak, of listening to his music. Most of these works are now to be heard in their original form, stripped of the veneer of "improvements" suggested to the diffident composer by his friends.

The masses, which translate Bruckner's symphonic ideas to the choral plain, and Bruckner's delightful string quintet are worth study.

Wagner.

Praised only this side of idolatry by his admirers, unmercifully criticised by his detractors, Richard Wagner (1813–83) is perhaps the most controversial composer in musical history. And so it was bound to be with such a revolutionary figure, whose writings, other than his music, contain, to say the least, dubious theories and whose operas, composed to his own libretti, broke the bonds of the form as known until his time. He regarded music-drama as a fusion of all the arts—music, literature, painting—in one unity. With *The Ring of the Nibelungs* he achieved his purpose; no other work of art has ever tried to encompass the whole of existence. Today, and surely forever, musicians, philosophers, and writers will argue over its meaning, and each age will reinterpret it according to its own lights.

His Transformation of Opera.

But before he reached this pinnacle of achievement, Wagner gradually transformed opera—through *Rienzi*, *The Flying Dutchman*, *Tannhäuser*, and *Lohengrin*—so that a new mould was fashioned to take what he wanted to pour into it. He introduced the *Leitmotiv*, a musical theme that could be associated with a particular person, situation, or idea, each time it occurred. Slowly he developed the musical form so that the drama could unfold continuously without breaks for arias. By the time he began to write *Tristan and Isolde* and *Die Meistersinger*, he had perfected his methods and had he never undertaken *The Ring* that tragedy and that comedy would have assured him his place in the musical firmament. Indeed, *Die Meistersinger* is considered a masterpiece even by those who are not willing or prepared to accept the rest of the Wagnerian ethos.

The length and complexity of these operas, and of *Parsifal*, a work of unique beauty in spite of certain *longueurs*, means that it is almost essential to prepare oneself by homework, with libretti and records, before attempting to assimilate them in the opera house. The added effort is well worth while for the ultimate musical satisfaction they bring because Wagner was more than an operatic reformer; he opened up a new harmonic language (especially in the use of chromaticism) that was logically to develop into the atonality of the 20th cent.

Wolf.

As Wagner was the culmination of the 19th cent. symphonic and operatic tradition, so Hugo Wolf (1860–1903) summed up, if he did not surpass, the achievements in song-writing of Schubert, Schumann, and Loewe (1796–1869).

Wolf was a lonely, pathetic man. He lived much of his life in poverty, and eventually lost his reason and died of an incurable disease. These circumstances account perhaps for his almost feverish bursts of creative activity, which were also the outward sign of his burning genius.

His greatest contributions to the art of *Lieder* were his extraordinary insight into the poet's meaning and the harmonic means by which he heightened the expression of the words. He raised the importance of the piano part even higher than had Schumann, and in some of his songs the vocal part takes the form of a free declamation over a repeated idea in the piano. However, in the main the vocal and piano parts are interweaved with great subtlety, and he unerringly matched the very varied moods of the poems he chose to set.

His greatest creative period was between early 1888 and early 1890 when songs poured from his pen daily more than 50 settings of the German poet Mörike, 20 of Eichendorff, more than 50 of Goethe, and more than 40 of Heyse and Geibel (the Spanish Song-book). Later he composed songs from Heyse's Italian Song-book and the three Michelangelo sonnets. And the range of his creative understanding was wide, taking in the almost wild passion of the Spanish songs, the humanity and humour of the Italian love-songs, the titanic power of *Prometheus* (Goethe), the varying moods of the Mörike book, and the intangible power of the Michelangelo sonnets. There are almost inexhaustible riches here for the inquiring mind to discover. Outside *Lieder*, Wolf 's output is small, but it includes a sadly neglected opera, *Der Corregidor*, the Italian Serenade for string quartet (alternatively for small orchestra) and a tone poem *Penthesilea*.

National Movements.

During the course of the 19th cent., alongside the emergence of national political identity, came the rise of nationalism in music, fertilising traditional Western—that is basically German—musical forms with folk material. Of these groups the Russian is certainly the most important, if not the most vital.

Glinka.

Glinka (1804–57) was the first important Russian composer of the national school and, although his two operas *A Life for the Tsar* (sometimes called *Ivan Susanin*) and *Russlan and Ludmilla* are strongly influenced by Italian models, they do introduce Russian song and harmony into the texture. He undoubtedly influenced Borodin (1833–87), Cui (1835–1918), Balakirev (1837–1910), Mussorgsky (1839–81) and Rimsky-Korsakov (1844–1908)—the so-called "Five" of 19th-cent. Russian music.

Each was very much an individualist too. Borodin was a lecturer in chemistry who wrote in his spare time. His two symphonies, two string quartets led up to his most notable work, the opera *Prince Igor*, left incomplete at his death. Balakirev, a friend and adviser to the rest of the group, wrote little himself, but his orchestral works and the piano fantasia, *Islamey*, are worthy of investigation.

Mussorgsky.

Modest Mussorgsky (1839–81) is today seen as the most important and inspired of "The Five." More than the others he used Russian song and Russian speech as the basis of his operas in which he portrayed the lives and destinies of his own people. Although his capacities were seriously impaired by an uncongenial job, poverty, and drinking, he produced two great operas, *Boris Godunov* and *Khovanshchina*, and another *Sorochintsy Fair* that is immensely enjoyable. *Boris* should be given in its original, with spare orchestration, but more often than not it is heard in Rimsky-Korsakov's more elaborate revision. In any case the opera exists in various versions, none of them necessarily the right one; what is important is to hear it in one or the other because of its great portrayal of Boris's personality set against the background of the Russian people, unforgettably presented in choral outbursts. *Khovanshchina* was completed by Rimsky-Korsakov, *Sorochintsy Fair* by Tcherepnin (although other versions also exist). Mussorgsky's songs explore a new vein of naturalistic vocal declamation. Each of the four *Songs and Dances of Death* is a miniature drama worthy of Wolf, although of course in a quite other idiom. The *Nursery* songs miraculously conjure up a child's world as seen from a child's point of view. Many of the individual songs, the *Sunless* cycle too, should be investigated.

Rimsky-Korsakov.

Rimsky-Korsakov (1844–1908) is perhaps a less attractive figure because so much of his music seems heartless or merely decorative, but this judgment is probably made on the strength of hearing *Shéhérazade* and the *Capriccio Espagnol* a few too many times. Such of his 15 operas as are played evince a (literally) fantastic mind and lyrical vein, and it is a pity that *Sadko*, *The Snow Maiden*, and *The Tsar's Bride*, at least, are not heard more often.

Tchaikovsky.

Peter Ilyich Tchaikovsky (1840–93) is a more universally admired figure than any of "The Five" and his music is indubitably closer to the mainstream than theirs in that it adheres more nearly to Western European forms. His popularity is due to his unhesitating appeal to the emotions and to his tender, often pathetic melodic expression. His lyrical gift is stronger than his sense of architecture, as he himself admitted. Yet his later symphonies—the fourth, fifth, and sixth (the *Pathétique*)—are all cogently enough argued and invigorating, as can be heard in the hands of a conductor willing to emphasise their formal power rather than their tendency towards sentimentality; the orchestral craftsmanship is also superb.

The three piano concertos and the violin concerto offer rare opportunities for virtuoso display within a reasonably dramatic structure and his various overtures are always exciting to hear.

The three ballets—*The Sleeping Beauty*, *Swan Lake*, and *Nutcracker* show Tchaikovsky's skill on a smaller and perhaps more congenial scale, but only two of his operas—*Eugene Onegin* and *The Queen of Spades* survive in regular performance. They demonstrate his ability to delineate character and his always eloquent melodic invention.

Smetana.

The Czech national school is dominated by two composers—Smetana (1824 84) and Dvořák (1841–1904). In his own country Smetana holds a unique position as the father of his country's music -which is remarkable when you consider that he lived in a country that was then under Austrian rule and never spoke the Czech language perfectly. Yet his music is filled with the spirit of Czech history and national life, and many of his operas, his most important contribution, deal purely with national subjects. The reawakening of interest in things national, after Austria's defeat by Italy in 1859, led to the establishment of a Provisional Theatre in 1862 and Smetana's first opera *The Brandenburgers in Bohemia* was produced there in 1866, but its success was eclipsed by the enormous popularity of *The Bartered Bride*, which appeared the same year. Its melodic charm, lively characterisation and cosy humour have carried it round the world and it is the one Smetana opera to be in the repertory of most opera houses. However, his next opera *Dalibor* (1868) is considered by some authorities as his masterpiece. It is conceived on a heroic scale, and frequently rises to great dramatic heights.

His later operas include *Libuse* (1872) a solemn festival tableau, *The Two Widows* (1874), a delightful comedy, *The Kiss* (1876), *The Secret* (1878), and *The Devil's Wall* (1882).

His Orchestral Work.

His main orchestral work *Má Vlast* (My Country), written between 1874 and 1879, is a cycle of six symphonic poems nobly depicting the life and legends of his country. He composed only three mature chamber works—an elegiac piano trio, written in 1855 in memory of the death of his eldest daughter, and two string quartets, both autobiographical. The first in E minor (1876)—"From My Life"—tells of his youth and aspirations until a terrible, screeching E in *altissimo* describes the onset of deafness; the second in D minor, sadly neglected, was described by the composer as an attempt to explain the "whirlwind of music in the head of one, who has lost his hearing," and was probably influenced by Beethoven's later music.

Dvořák.

Dvořák combined a fecund melodic gift with an intelligent grasp of structure. His symphonies and chamber music are mostly written in classical form, yet the works are imbued with a spontaneity and freshness that have not lost one whit of their charm over the years.

He wrote nine symphonies and, although only the last three or four are regularly performed, they are mostly mature works, several of which, for instance No. 7 in D minor (formerly known as No. 2) reach a tragic grandeur at times. They are all orchestrated in a masterly way and are full of delightful detail. Dvořák wanted to show that a Brahms could come out of Bohemia—and he succeeded in doing so while maintaining a definitely individual flavour, strongly influenced by natural rhythms.

He wrote three concertos, one each for piano, violin, and cello. The earlier ones are interesting without being quite in the first flight of the composer's output, but the cello concerto of 1895 is perhaps the composer's crowning achievement—warm, mellifluous, romantic.

He wrote chamber music throughout his long creative life. Some of the early works are weak and derivative, but the later string quartets, the "Dumky" trio, and the piano quartet and quintet are expressive and full of unforced invention. Dvořák felt himself somewhat hampered when setting words, nevertheless his *Stabat Mater* and *Te Deum* are both deeply felt choral works and he wrote songs throughout his career, many of them very fine indeed. He wrote ten operas, but only *Rusalka* (1901) is internationally known.

Janáček.

The Moravian composer Leos Janáček (1858–1928) spent most of his life in Brno as a working musician. His music has recently come to be recognised as some of the most original written in the past hundred years. His operas, in which he closely followed the inflection of the speech of his native land, are his finest works. Over the score of his last opera, *From the House of the Dead*, he wrote the words "In every human being there is a divine spark", and it is this deep love of humanity that permeates all his works. Of his operas *Kátya Kabanová* (1921) and *The Cunning Little Vixen* (1924), the *Makropoulos Affair* (1926), and *From the House of the Dead* (adapted from a Dostoyevsky novel, 1928) are the most important and they have all been produced in Britain in recent years.

His original genius is very clearly self-evident in all of them.

Among his orchestral works *Taras Bulba* and *Sinfonietta* should be noted, and his two string quartets, very difficult to play, should be better known. The song cycle, *Diary of one who has disappeared*, for tenor, contralto, and three female voices with piano, and the Glagolithic Mass contain music of much expressive beauty.

Hungary: Bartók and Kodály.

The Hungarian musical outburst came somewhat later than that of other countries. Its great figure is Bela Bartók (1881–1945) who, as well as being a national figure, has proved an influential composer in the whole of 20th-cent. music. His mind was full of folk music, but it was transmuted by his strongly personal style and powerful intellect into something highly original. His music is tense and volatile but this restlessness is sometimes relieved by a kind of other-wordly, ethereal lyricism, as in the lovely slow movements of his quartets.

Bartók was affected as much by the musical innovations of Debussy and Stravinsky (*see below*) as by East European, notably Magyar, folk music. Many of his works are an attempt to meld the two together.

The most important part of his output is undoubtedly his string quartets which cover most of his creative life. To this intimate form he confided his personal innermost thoughts and in it conducted his most far-reaching musical experiments, thereby extending its boundaries beyond anything previously known. As with Beethoven's late quartets many of Bartok's rely on organic or cyclic development while remaining just within the laws of classical form. As Mosco Carner puts it, "For profundity of thought, imaginative power, logic of structure, diversity of formal details, and enlargement of the technical scope, they stand unrivalled in the field of modern chamber music."

The most important of his orchestral works are the three piano concertos, of which the first two are harsh and uncompromising, and fiendishly difficult to play, while the third, written in 1945, is mellower and more diatonic. The second violin concerto (1937–8) shows the various elements of Bartók's style in full flower, by turns exuberant, passionate, and brilliant. The *Music for Strings, Percussion and Celesta* (1937) is remarkable for its strange sonorities and its fascinating texture. The *Concerto for Orchestra* (1944) is more immediately appealing and again shows the composer in complete command of a large canvas. Of the piano works *Mikrokosmos* (1935) and the sonata for two pianos and percussion (1937) are worth investigating.

His chief stage pieces are *The Miraculous Mandarin* (1919), a harsh, cruel ballet which drew appropriately dramatic music from the composer, and the opera *Duke Bluebeard's Castle* (1911), a luscious, original score that makes one regret that he wrote no more operas later in his career for our pleasure.

Kodály (1882–1967) was from early years closely associated with Bartók and with him collected Hungarian folk melodies using many of them in his music. He worked in many forms and the more important of his works are the *Peacock Variations* for orchestra, the choral *Psalmus Hungaricus* and *Te Deum*, The *Dances of Galánta*, and the opera *Háry János*, and the sonatas for cello and for unaccompanied cello.

Sibelius, Nielsen and Grieg.

Among Scandinavian composers the Finn Jean Sibelius (1865–1957) and the Dane Carl Nielsen (1865–1931) are outstanding. Sibelius is a lone northern figure ploughing his own furrow oblivious or, at any rate, ignoring the unusual developments that were taking place in Central Europe, yet his seven symphonies are strong as granite, honest, rugged works that will undoubtedly stand the test of time. They are not by any means all similar in mood, or even form. The first is very much influenced by Tchaikovsky and Borodin, the second and third show a more personal style developing, the fourth is terse and tragic, the fifth lyrical, bright, and lucid; the sixth is perhaps most typically Sibelian in its evocation of primeval nature, and the seventh—in one continuous movement—is a more purely abstract piece, notable for its structural logic and the grandness of its themes. The violin concerto is the most easily understood of the composer's main works and has a grateful part for the soloist.

The tone poems *The Swan of Tuonela*, *Pohjola's Daughter*, *En Saga*, *Night Ride and Sunrise*, *The Bard*, and *Tapiola* uncannily evoke the icy words of the legends of the far north, and the primeval forces of nature. Sibelius's one string quartet *Voces Intimae* and many of his songs are worth hearing too. His music, reviled in some quarters during the 1950s, has since been restored to favour, and seems to be enjoyed again by critics and the general public alike.

Carl Nielsen (1865–1931) is another individualist. His six symphonies, like Sibelius's seven, are the most important part of his output, but whereas Sibelius was dealing with a huge, uninhabited northern landscape, Nielsen is more friendly and serene in his music, which is seldom forbidding, always inventive, throwing a new light, through unusual ideas about harmony, structure and tonality, on traditional forms. He also wrote highly individual concertos for the flute and clarinet, four string quartets and two operas—the dramatic, rather Brahmsian *Saul and David* (1902) and a delightful comedy, *Maskarade* (1906), full of lyrical music.

Edward Grieg (1843–1907), the Norwegian composer, was essentially a miniaturist whose range of feeling was not wide but whose music is always gentle and appealing. His most notable works are the romantic piano concerto, the atmospheric incidental music to Ibsen's play *Peer Gynt*, the charming Lyric Suite, and the small piano pieces.

Elgar and the English Revival.

After the death of Purcell there is hardly a name in English music worth speaking of until the 19th cent. when Hubert Parry (1848–1918) and Charles Villiers Stanford (1852–1924), actually an Irishman, led a revival. Their music is seldom heard today, but their pioneer work paved the way for Edward Elgar (1857–1934). Although all were influenced by Brahms they nevertheless managed to establish a new English tradition that has been carried on in our own day. Elgar's symphonies are laid out on a grand, leisurely scale and they are both eloquent and exhilarating. His violin concerto has an elegiac slow movement as has the glorious cello concerto and both contain many fine opportunities for the soloist. The cello concerto is as appealing a work as any by Elgar expressing his innermost thoughts. His *Enigma Variations* are a series of portraits in sound of his friends, but there is another overall theme to go with them that has never been identified. This has not prevented the work from becoming Elgar's most popular, not surprisingly when one considers its charm and melodiousness.

Three other orchestral pieces that should not be neglected are his symphonic study *Falstaff*, a many-sided musical picture of the Fat Knight, and the overtures *Cockaigne*, a happy evocation of London, and *In the South*, inspired by a visit to Italy. His three late chamber works, written when he was 61, are reticent, economic pieces that remove any misconception of Elgar as a bombastic composer. His songs are mostly feeble, but the oratorios, notably *The Dream of Gerontius*, show the composer's ability to control a large canvas.

French Music.

The Belgian César Franck (1822-90) was the main figure in mid-19th-cent. France. His influence spread even wider than his music of which only the D minor Symphony, the Symphonic Variations for piano and orchestra, the piano quintet, and the violin sonata are likely to be encountered today. The leading French opera composers of that time were Gounod (1818-93), Bizet (1838-75) and Massenet (1842-1912). Gounod's *Faust*, Bizet's *Carmen* (composed just before his untimely death when he caught cold after a swim) and Massenet's *Manon* all retain a deserved place in the repertory; each is a well-judged mini-drama unafraid of romantic ardour and forceful, histrionic strokes. Some of Massenet's other numerous operas, such as *Werther* and *Don Quichotte*, have enjoyed a revival in recent years.

Debussy.

Concurrently with similar movements in French painting and poetry came the French Impressionist composers at the end of the 19th cent. Their leader—and one of the great seminal forces of modern music—was Claude Debussy (1862-1918). His aim was to capture a mood or sensation, and he did that by more or less inventing a fresh system of harmony using a whole-tone scale, unusual chords, and by creating in the orchestra new, highly personal textures—there is no mistaking the Debussy idiom once you have heard at least one piece by him. His impressionistic style did not lead him, however, to abandon form as some have suggested, and his main works are just as closely organised as those by classical German composers. His music is sensuous and poetic yet nearly always structurally satisfying as well.

His reputation, at least with the general musical public, rests largely on his orchestral music, a few piano pieces and his only opera *Pelléas et Mélisande*. *La Mer* is a scintillating evocation of the sea in all its moods; *Nocturnes*, *Images*, and *Prélude à l'Après-midi d'un Faune* exactly suggest different places, times, moods—the "Iberia" and "Gigues" sections of *Images*, calling to mind respectively the spirit of Spain and the flickering light of a rainy English night. *Pelléas*, based on a Symbolist drama by Maeterlinck, tells a story of love, jealousy, and murder in predominantly restrained yet emotionally loaded terms. It is an elusive original work that has no predecessor or successor. Intensely atmospheric, rivetingly beautiful, it weaves an irresistible spell over the listener.

Debussy's chamber music is unjustly neglected. His string quartet (1893) was one of the first works in which he displayed his new and strange world of sound, and the three late sonatas, one for violin, one for cello, and the third for flute, viola, and harp are elliptical, compressed pieces which seem to be questing disjointedly into new regions of sound. His songs too, are worthy of investigation, and his piano music, especially the twenty-four Preludes and some of the shorter pieces, contain some of his most imaginative and original ideas and thoughts.

Gabriel Fauré (1845-1924) is a difficult figure to place. He lived through all kinds of musical revolutions yet they seemed to affect the character of his work very little. He has never been, and is never likely to be, a widely known or popular composer, yet his music has a reticience and delicacy that is very appealing. Despite his dreamy, retiring art he was not a recluse, but a very sociable man.

He was content with forms as he found them, but he imbued them with a very personal, human style. Perhaps his art is best heard in his songs. They are not overtly passionate or dramatic but the long, sinuous melodies and subtle harmonies are exquisitely wrought. Of the song-cycles, *La Bonne Chanson*, *Cinq Mélodies* (Verlaine), *Le Chanson d'Eve*, and *L'Horizon Chimérique* are best known. The last written in 1922, when the composer was seventy-seven, is a beautiful setting of words by a soldier killed in the first World War. There are also many remarkable single songs, many of them settings of poems by Verlaine. His opera *Pénélope*, based on the classical heroine, is unjustly neglected.

He wrote few orchestral pieces, but the *Ballade* for piano and orchestra and the *Pavane* are among his most typical, and delicate compositions, and his outstanding piano music, modelled on Chopin's, includes Nocturnes, Impromptus, and Barcarolles. His chamber music covers more than half a century from the violin sonata of 1876 to the string quartet written the year he died. In that period he composed two piano quartets, two piano quintets, another violin sonata and two cello sonatas, the later works failing to show quite the unforced lyrical grace of the earlier ones. Perhaps Fauré is best approached with the first piano quartet, a charming, easily assimilated work, and the beautiful choral *Requiem*.

Saint-Saëns (1835-1921), an accomplished, cultivated musician, has had a "bad press" but his craftsmanship, as displayed in his symphonies, concertos, and *Samson et Dalila* (one among his 12 operas) is not to be despised.

Henri Duparc (1844-1933), despite a very long life, is known today only for a group of songs he wrote before he was forty. They are among the most emotionally direct yet tasteful melodies ever written. Paul Dukas (1865-1935) is another figure off the beaten track, as it were. He, too, is known only for a handful of compositions. He was strongly influenced by Vincent d'Indy (1851-1931) and the school who strongly opposed Debussy's new ideas, yet he could not help but come under Debussy's spell. Dukas's one great work is his opera *Ariane et Barbe-Bleue*, the text adapted from a Maeterlinck play written with the composer in mind.

Maurice Ravel (1875-1937), a pupil of Fauré, followed in Debussy's footsteps, although his later pieces were more ascetic. Indeed, he was one of the most fastidious of composers, always seeking, and often finding, artistic perfection. The works he wrote before 1918 are definitely of the Impressionist School and it would be difficult to imagine more beautiful sounds than are to be found in the ballet *Daphnis el Chloé*, in the song-cycle *Shéhérazade*, and the piano fantasy *Gaspard de la Nuit*. His first style was summed up in the A minor piano trio (1915). In his later music Ravel was struggling, not always successfully, to keep up with new developments such as jazz and atonality. The piano concerto, for instance, shows very strongly the influence of jazz.

Outstanding orchestral works of his, other than *Daphnis* are *Rapsodie espagnole* (1907), *La Valse* (1920), a sumptuous evocation of the Vienna waltz, and the ever-popular *Boléro*. Two chamber works, besides the trio, are masterpieces—the string quartet (1902-3) and the Introduction and Allegro for Harp, String Quartet, Flute, and Clarinet. This Septet composed in 1906, ravishes the senses with magical sound.

Ravel's piano pieces are perhaps his most notable contribution to music, combining an extraordinary feeling for the instrument's technical possibilities with the sensibility of a Chopin, and in this field *Jeux d'eau*, *Miroirs*, and *Ma Mère l'Oye*, all written just after the turn of the century, come very close to the perfection of *Gaspard de la Nuit*. His songs show his unusual appreciation of the need to fuse poetic and musical values, and he set exotic poems for preference.

His work in this field includes the cycle *Histoires naturelles* (1906), acutely observed settings of five poems about birds and animals; *Cinq Mélodies populaires grecques* (1907), charming settings of Greek folk songs; *Trois Poèmes de Mallarmé* (1913); and *Chansons madécasses* (1926), suitably exotic settings of three poems by an 18th-cent. Creole poet called Parny. Finally in 1932 came *Don Quichotte à Dulcinée*, three poems by Paul Morand, Ravel's last composition.

Ravel wrote two operas—the slight but moderately amusing *L'Heure espagnole* (1907), nicely orchestrated in a faintly and appropriately Spanish style and *L'Enfant et les Sortilèges* (1925) to a story by Colette, a delicious fantasy about a naughty child who gets his due punishment for tormenting animals and destroying furniture.

French music after Debussy and Ravel was dominated by the slighter composers known as *Les Six*, the most important of whom were Arthur Honegger (1892–1955, Swiss born), Darius Milhaud (1892–1974) and Francis Poulenc (1890–1963). Each has contributed music of some wit and charm to the repertory. They were influenced by Erik Satie (1866–1925), an eccentric but interesting figure who wrote works with odd titles such as *Three Pear Shaped Pieces*. His music is entirely unsentimental, often ironic.

Spain.

Felipe Pedrell (1841 1922) has been aptly described as the midwife of Spanish nationalist music. As a musicologist and teacher he strongly influenced the two main composers of the school, Manuel de Falla (1876–1946) and Enrique Granados (1867–1916). Falla's output was not large and most of it was written around the years of the first world war. The pre-war years were spent in Paris where Falla came under the influence of Debussy. However his style is individual and evokes all the passion and gaiety of his native land. Perhaps his most typical works are in two ballets *Love the Magician* (1915) and *The Three-Cornered Hat* (1919). The opera *La Vida Breve* (1905) despite its weak libretto also has much appeal. The vivacity and smouldering passion at the heart of the country's character is conjured up by the *Seven Popular Songs* (1914) and the *Nights in the Gardens of Spain* (1916) for piano and orchestra. His later works, especially the harpsichord concerto of 1926, show Falla tending towards a less ebullient, more restrained style. The second opera, *Master Peter's Puppet Show* (1923) is a miniaturist work, refined and intense. His third opera *Atlantida*, left unfinished at his death, was completed by his pupil Ernesto Halffter and first staged in 1962.

Granados was perhaps a more restrictedly Spanish composer than Falla, but his music is unfailingly attractive and deserves to be better known. The opera *Goyescas* (1916) is most famous for the second interlude and opening of Act III—*La Maja y el Ruiseñor* (The Lover and the Nightingale), a haunting, sinuous melody for soprano, generally heard in its original form as a piano solo.

The chief claim to fame of Albéniz (1860–1909) is *Ibéria*, masterly descriptive pieces for piano. Many of his other piano works are now more well known in the form of very effective guitar arrangements.

Turina (1882–1949), attempted a more cosmopolitan style, but his most often heard music is typically Spanish.

The Late German Romantics.

While composers such as Debussy, Sibelius, Stravinsky and Schoenberg (see below for the latter pair) were striking out along new paths, Richard Strauss (1864–1949) continued in the trend of 19th-cent. German composers; he was the tradition's last great figure. At least two of his operas—*Salome* and *Elektra*—were considered shocking at the time, but today we can hear that they are essentially big-scale, romantic works—natural successors to Wagner's—however startling the harmonies may once have seemed.

If Strauss did not achieve the granite intellectual greatness of Beethoven or Wagner, there is no denying his melodic genius and powers of fertile invention which overlaid the streak of vulgarity and inflation in his musical make-up. His first outstanding achievement was in the field of the symphonic poem, where he carried the work of composers such as Liszt and Berlioz to its logical conclusion. Starting with *Don Juan* in 1888 and ending with *Sinfonia Domestica* in 1903 he wrote a series of kaleidoscopic works, full of enormous vitality, endless melody, and fascinating orchestration. The most easily assimiliated—and the most popular—are *Don Juan* and *Till Eulenspiegel* but some of the longer works, notably *Also Sprach Zarathustra* (based on Nietzsche's prose poem) and *Don Quixote* (based, of course, on Cervantes's great work) will reward the persistent, inquiring mind with long hours of enthralled listening. Other works sound somewhat dated in their bombastic over-confidence, though Strauss's skill in composition seldom flagged at this stage of his long creative career.

The symphonic poems all tell something of a story usually based on a literary source, but it is not essential to the enjoyment of the music to know what this is, although it may be helpful.

The Reputation of Strauss.

Strauss's reputation is even more solidly based on his fifteen operas, the earliest of which *Guntram* was first performed in 1894, the last, *Capriccio*, in 1942. During these years the essentials of Strauss's style changed little, though it became very much more refined as the years passed. His first operatic period ended with the violent, sensual tragedies *Salome* (1905) and *Elektra* (1909), the latter being his first collaboration with his chief librettist, Hugo von Hofmannsthal. Then came their unique *Der Rosenkavalier* (1911), which filters the charm and the decadence of 18th-cent. Vienna through early 20th-cent. eyes. This was followed by *Ariadne auf Naxos* (1912). Originally intended to be given after Molière's *Le Bourgeois Gentilhomme*, it was later presented (1916) without the play but with an amusing Prologue, written by von Hofmannsthal. *Die Frau ohne Schatten* is the most grandiose result of the Strauss–Hofmannsthal partnership. It is a complex psychological allegory, but Strauss's contribution is not on as consistently lofty a level as is his librettist's. *Intermezzo* (1924), which has a libretto by Strauss himself, is a largely autobiographical domestic comedy, which has lately gained in reputation as a compact, charming piece.

With *Die Aegyptische Helena* (1928), an opera on a mythical theme, and *Arabella* (1933), another sensuous Viennese comedy, the Strauss–Hofmannsthal collaboration ended on account of the librettist's death.

Strauss then wrote *Die Schweigsame Frau* (1935) to a libretto by Stefan Zweig, based on a play by Ben Jonson, and *Friedenstag* (1938), *Daphne* (1938)—a beautiful opera—and *Die Liebe der Danae* (written 1938–40) with Josef Gregor as librettist. His swan-song was *Capriccio*, a dramatisation of the old argument about the relative importance of words and music in opera. The libretto is by the conductor Clemens Krauss and the opera, a serene, melodious work, was a fit end to a great operatic career.

However, Strauss went on composing till nearly the end of his life, adding a group of late orchestral pieces to his already large catalogue of works. The *Metamorphosen*, for 23 solo string instruments, is probably the best of these. During his long creative career he wrote numerous songs, many of them, such as *Morgen*, *Wiegenlied* and *Ruhe, meine Seele* of surpassing beauty.

Reger and Pfitzner.

Other notable figures in German music at this time were Max Reger (1873–1916), a somewhat ponderous but highly accomplished composer who, in a quarter of a century of creative life, wrote more than 150 works, of which his sets of variations, his piano concerto, and chamber music are probably the most impressive. Hans Pfitzner (1869–1949), another German traditionalist, is chiefly remembered today for his opera *Palestrina*, about events, now known to be spurious, in the life of the 16th-cent. Italian composer.

Gustav Mahler.

Gustav Mahler (1860–1911), the Austrian Jewish composer, is one of the most important figures in 20th-cent. music. In a sense he bridges the gulf between the late Romantics, who were tending more and more towards chromaticism and away from established key relationships, and the atonalists, who abandoned the key system entirely. His detractors maintain that his inflation of allegedly banal Viennese beer-house music to unheard-of lengths rules him out of court as a serious writer. His admirers would claim that his music encompasses the whole of life in enormous, valid structures. The truth, if truth there be, perhaps lies somewhere in between: if his material does not always justify the length of his symphonies, and if there are occasional imperfections and *longueurs*, these shortcomings are worth enduring for the sake of the depth of utterance, the humanity and the poetry of the great pages.

His music is undoubtedly best approached through his songs, where the words force him to discipline his wide-ranging vision. *Lieder eines fahrenden Gesellen* (1884), to his own words, *Kindertotenlieder* (1901–4), to poems by Rückert, and some individual songs perfectly relate words to music, and are all of a poignant loveliness. Similarly *Das Lied von der Erde* (1908), especially the last of the six songs, is a touching farewell to the world, nobly expressed.

Mahler's Symphonies.

The ten symphonies, however, are Mahler's most impressive legacy to posterity. They are almost impossible to characterise briefly so vast are they in terms of both length and variety. The first, fourth and ninth are probably the easiest to grasp but the fifth, sixth and seventh, despite flaws, contain some of his most awe-inspiring conceptions. The second and third, both of which use soloists and chorus, are revolutionary in orchestration and structure; they both try, inevitably without complete success, to carry out the composer's dictum, "a symphony should be like the world -it must contain everything." The eighth is even more gargantuan, but as in all Mahler's work size does not mean loss of clarity or an overloading of the structure. Part one—a mighty choral invocation—is a visionary setting of the mediaeval hymn *Veni Creator Spiritus*. Part two, which incorporates adagio, scherzo, and finale in one, is a setting of the final scene of Goethe's *Faust*. Until recently all of Mahler's unfinished tenth symphony that was ever performed was the Adagio, but the musicologist and Mahler scholar, the late Deryck Cooke, provided a performing version of the symphony to critical and popular acclaim during the 1960s and thus added a noble, and also optimistic epilogue to the Mahler opus. The debate over the quality of Mahler's music is likely to continue; one fact, however, that cannot be gain-said is his popularity with an ever-increasing audience, largely made up of young people. There must be something in his uncertainty and intense self-inquiry that appeals.

Schoenberg and the Second Viennese School.

Arnold Schoenberg (1874–1951) revolutionised Western music by his twelve-note method—a system which uses all the notes of the chromatic scale "and denies the supremacy of a tonal centre," as Schoenberg himself puts it. This serial technique of composition, as it is commonly called, naturally sounds strange to an ear acclimatised to music written, as it were, with a home base, but Schoenberg and his disciples Berg and Webern showed that the system could produce works that were something more than mere intellectual exercises. None of the recent advances in music would have been possible without Schoenberg.

Schoenberg always considered himself as much as a composer as a theorist or teacher, and his works are supposed to appeal as much to the emotions as to the intellect, although to be understood they do, of course, require the listener's concentrated attention. To appreciate how his ideas developed it is necessary to hear first his pre-atonal music, such as the *Gurrelieder* (1900–1) and *Verklärte Nacht* (1899), in which he carried Wagnerian chromaticism to extreme lengths. The *Gurrelieder*, in particular, is a luxuriant, overblown work that shows the Wagnerian idiom in an advanced stage of decay, in spite of many beautiful pages of music. In his succeeding works the feeling of tonality began to disappear until in the Three Piano Pieces (opus 11), of 1909, he finally rejected tonality, although the new 12-note scheme is not yet evident; traces of the old order can still be heard. The succeeding works were mostly short, highly compressed, and very expressive. Schoenberg was reaching out for a new system, which would "justify the dissonant character of these harmonies and determine their successions." By 1923 he had formulated his 12-note system and the Five Piano Pieces (opus 23), and the Serenade (opus 24) of that year, can thus be considered the first works that used a note-row as the fundamental basis of their composition. Between 1910 and 1915, however, the Russian composer Alexander Skryabin (1872–1915) had attempted to define a new method of composition of his own employing the "mystic chord" of ascending fourths, but his scheme proved comparatively abortive when compared with Schoenberg's. Josef Hauer (1883–1959) also developed a 12-note system which he propounded in 1919 and he always considered himself, rather than Schoenberg, as the true founder of the system. He later worked out a system of tropes (*i.e.*, half-series of six notes).

Schoenberg's Later Work.

To return to Schoenberg, in later works he shows much more freedom and assurance in the use of his system. The wind quintet (1924), the Variations for Orchestra, opus 31 (1927–8), the third (1926), and fourth (1936) string quartets, and the string trio (1946) are modern classics of their kind; they require concentrated listening and a degree of understanding of the unfamiliar style of composition. The set of songs with piano *Das Buch der hängenden Gärten* (opus 15), written in 1908, *Pierrot Lunaire*, opus 21 (1912) and the Four Songs, opus 22 (1913–14) provide a kind of bridge between tonality and atonality that the adventurous mind should cross. The monodrama *Erwartung* (1909) is another fascinating work, but perhaps the unfinished *Moses and Aaron* (1932) is Schoenberg's masterpiece as its production at Covent Garden in 1965 showed. Here, for certain, the composer matched his obvious intellectual capacities with an evident emotional content and managed to combine *Sprechgesang* (speech-song) and singing with a real degree of success.

It is only in recent years that Schoenberg's music has had a real chance to make its mark through the essential prerequisite of frequent performance. If his idiom now seems approachable, and a reasonably natural outcome of late 19th-cent. developments, it is perhaps because other, more recent composers have extended the boundaries of sound much further.

Disciples of Schoenberg.

Schoenberg's two most respected disciples were Anton Webern (1883–1945) and Alban Berg (1885–1935). Webern's output is small, reaching only to opus 31, and many of his works are very brief. They are exquisitely precise, and delicate almost to a fault. He was trying to distil the essence of each note and in so doing carried the 12-note system to its most extreme and cerebral limit. His music has often been described as pointillist in the sense that one note is entirely separated from the next, there being little discernible melody. Beyond Webern's music, there is indeed the sound of nothingness, and he was rightly described during his lifetime as the "composer of the *pianissimo espressivo*". In his later works, Webern tended towards a strict, and often ingenious use of form and the Variations for Orchestra of 1940 are a good example of this and of his delicacy of orchestration. Webern's influence has perhaps been greater than the impact of his own music, even though he has had no direct successor.

Berg's music is much more accessible. Like Webern his total output was not large, but nearly all his works are substantial additions to the repertory. He is also the directest link between Mahler and the second Viennese School, as Mahler's music influenced him strongly. He studied with Schoenberg from 1904 to 1910. His music is more intense, more lyrical, and less attenuated in sound than Schoenberg's or Webern's. His humanity and abiding compassion can be heard most strongly in his finest opera *Wozzeck* (1925) and his violin concerto (1935), written as an elegy on the death of Manon Gropius, a beautiful 18-year-old girl. Both works are very carefully designed yet formal considerations are never allowed to submerge feeling, and the note-row is fully integrated into the structure.

Both *Wozzeck* and the unfinished but rewarding *Lulu* are concerned with society's outcasts who are treated with great tenderness in both operas. The later work is entirely dodecaphonic, all the opera's episodes being based on a theme associated with Lulu. Between these operas Berg wrote the highly complex Chamber Concerto for piano, violin, and thirteen wind instruments (1925) and the expressive Lyric Suite (1926). Among his other works the Seven Early Songs (1908–9) and the concert aria *Der Wein* (1929) are notable.

Stravinsky.

Igor Stravinsky (1882–1971) was another vital figure in 20th-cent. music. If his influence has been in quite another and perhaps less drastic direction than Schoenberg's it is hardly less important. Indeed, future musical historians may consider his achievement the more significant. He has been compared with the painter Picasso in his almost hectic desire to keep up with the times, yet, although he wrote in a number of very different styles over a period of fifty years, every work of his is stamped with his own definitive musical personality. His most revolutionary and seminal work is undoubtedly *The Rite of Spring* (written for the ballet impresario Diaghilev), which caused a furore when it first appeared in 1913, and although it no longer shocks, the rhythmical energy, the fierce angular thematic material, and the sheer virtuosity of the orchestration will always have the power to excite new audiences. Before *The Rite* Stravinsky had written two ballets for Diaghilev—*The Firebird* and *Petrushka*—that are no less filled with vitality and new, albeit not so violent, sounds. During the next thirty years Stravinsky wrote a series of ballet works, gradually becoming more austere and refined in composition. *Apollo* (1928) and *Orpheus* (1947) belong among his best scores.

The Versatility of Stravinsky.

Stravinsky did not confine himself in stage works to the ballet. *The Nightingale* (1914) is a charming, early opera; *The Soldiers Tale* (1918) is a witty combination of narration, mime, and dance; *Les Noces* (1923) is a concise, original choreographic cantata for soloists and chorus; *Oedipus Rex* (1927) is a dignified version of the Sophocles play, which can be staged or given on the concert platform; either way it is a moving experience. *Perséphone* (1934), a melodrama for reciter, tenor, chorus, and orchestra is an appealling, lucid score. After the war his most important stage work by far was *The Rake's Progress* (1951), with a libretto by W. H. Auden and Chester Kallman. This fascinating opera is deliberately based on 18th-cent. forms and the music itself is neo-classical, always attractive, often haunting.

Stravinsky was no laggard in writing for the concert-platform either. The finest of his orchestral pieces are probably the fervent choral *Symphony of Psalms* (1930), the violin concerto (1931) and the aggressive compact Symphony in Three Movements (1945). Of his chamber music the octet (1923), a duo concertant (1932), and septet (1952) are probably the most important, but no piece, even the dryest and most pedantic, is without redeeming features.

Stravinsky is often thought of as an aloof, detached figure. He has been castigated for his lack of lyrical warmth. But in spite of his own professed desire to drain his music of specific emotion, craftsmanship and originality, often with a strange other-worldly beauty added, are unmistakably there throughout his many scores.

Busoni.

Italian music in the early part of the century was dominated by two very different composers—Ferruccio Busoni (1866–1924) and Giacomo Puccini (1858 1924). Busoni is a difficult figure to place. His austere, intellectual power is never called in question, but he seldom, if ever, succeeded in translating his technical prowess into altogether successful compositions. We can admire the strength, honesty, and often beauty of such works as his huge piano concerto (1903–4), *Fantasia Contrappuntistica* (1912)—for piano solo—and his unfinished opera *Doktor Faust* without ever capitulating to them entirely. None the less, it has to be admitted that those who have studied his music closely have always fallen completely under his spell. In style his music is anti-Romantic and often neo-Classical yet he was an ardent admirer of Liszt and more especially of Liszt's realisation of the possibilities of the pianoforte. Busoni, himself a great pianist, carried on where Liszt had left off in his own piano music, in which form and expression often find their perfect balance. *Doktor Faust* is undoubtedly his most important opera but *Die Brautwahl* (1908–10) and *Turandot* (1917) have many points of interest too.

Puccini.

Puccini's *Turandot*—his last opera—is a much grander version of the same Gozzi fable and the culmination of this great opera composer's work. His achievement is at an almost directly opposite pole to Busoni's. Not for him the severity or intellectuality of his contemporary. He sought and found an almost ideal fusion of straight-forward lyricism and dramatic truth. His music unerringly follows the pathos and passion of the stories he sets and all his characters "live" as human beings. That, and his abundant flow of easy, soaring melody, are the reasons for his immense popular success, unequalled by any other 20th-cent. composer. Whether it is the pathetic Mimi (*La Bohème*—1896) and Cio-Cio-San, (*Madam Butterfly*—1904), the evil Scarpia (*Tosca*—1900), the cunning Schicchi (*Gianni Schicchi*—1918), the ardent Rodolfo (*La Bohème*) and Cavaradossi (*Tosca*), or the ice-cold Turandot (*Turandot*—1926). Puccini's musical characterisation is unfailing. And he backs his *verismo* vocal writing with an orchestral tissue that faithfully reflects the milieu of each opera, for instance, Japanese for *Butterfly*, Chinese for *Turandot*, while never losing his particular brand of Italian warmth. His orchestration is always subtle and luminous.

Other Italian composers who wrote operas in the *versimo* style of Puccini were Leoncavallo (1858–1919), Mascagni (1865–1945), and Giordano (1867–1948). Mascagni's *Cavalleria Rusticana* and Leoncavallo's *Pagliacci* are both widely performed.

Prokofiev.

Sergey Prokofiev (1891 1953) spent part of his creative life in his native Russia, part of it (1918–34) abroad, mostly in Paris. His early music, apart from the popular Classical Symphony (1916–17) tended to be acid and harsh, but on his return to Russia his style, though still frequently satirical, became warmer, more Romantic. The third piano concerto (1917) and the second symphony (1924) are good examples of the former period, the ballets *Romeo and Juliet* (1935) and *Cinderella* (1941–4) and the fifth (1944) and sixth (1946) symphonies of the latter. His music gives the impression of immense rhythmical energy, as in the outer movements of several of his nine piano sonatas, but this fierce drive is often leavened by the soft, wistful lights of his slow movements. His second string quartet (1941), perhaps, presents all the elements of his music in the kindest light.

His strong leaning towards fantasy and mordant parody is felt in his earlier operas *The Love of the Three Oranges* (1921) and *The Fiery Angel* (1922–5). Towards the end of his life much of Prokofiev's music fell into official disfavour.

Shostakovich.

Dmitri Shostakovich (1906–75) also suffered from attacks on his style. He had to conform to Stalin's requirements for writing music, but he survived and continued to produce music of universal significance, for example, his later string quartets. Like Prokofiev, his music falls into two very distinct styles: one humorous and spiky, the other intense, very personal and often large-scale in its implications. Not all his symphonies reach the expressive depths of numbers one, five, six, eight, ten and fourteen, but they all have rewarding passages, and his violin and cello concertos are of high quality. He also wrote fifteen string quartets, a piano quintet (an attractive piece) and two operas: the satirical *The Nose* (1930) and *Katrina Ismailova* (1934, revised 1959), originally known as "Lady Macbeth of Mtsensk."

Rachmaninov.

Although Sergey Rachmaninov (1873-1943) was born in Russia, he left his home country in 1918, fearing the Soviet régime, and lived mostly in Switzerland and the United States (where he died). His music is chiefly notable for its Romanticism, nostalgic melody, nervous energy and, in the piano works, its opportunities for displays of virtuosity. The first three piano concertos, the third symphony, the piano preludes, and the Rhapsody on a theme of Paganini, are his most typical and attractive works, and many of his songs are touching and beautiful. He wrote three operas.

Weill and Hindemith.

Kurt Weill (1900–50) is chiefly known for his socio-politically pointed operas, such as *Die Dreigroschenoper* (1929), *Mahagonny* (1929), *Der Jasager* (1930) and *Happy End* (1929), all effective works on the stage, and for his particular brand of brittle, yet fundamentally romantic music. His influence on later composers has been considerable.

Paul Hindemith (1895-1963) in his later years wrote in a strictly tonal, often neo-classical idiom, after being one of the most advanced intellectuals of his time. As well as many chamber and orchestral works, he wrote three formidable operas: *Die Harmonie der Welt*, *Cardillac* and *Mathis der Maler*.

Ives and Copland.

Charles Ives (1874–1954) is generally recognised as the first American composer of major stature. Most of his works were composed before about 1920, while he was pursuing a successful career in insurance. Ives' music is noted for his thorough-going electicism and his refusal to be bound by rules and conventions. His work anticipates many 20th century techniques, such as polytonality and polyrhythm, which he seems to have arrived at independently of others. Folk song, hymn tunes, dance music and the sound of the brass band all appear in his compositions, many of which are evocative of his New England background (*e.g. Three Places in New England*, the *Holidays Symphony*, the *Concord* Sonata). It was not until the 1930s that Ives began to achieve recognition, but his influence on later American composers can hardly be exaggerated.

Aaron Copland (1900–90) was a composer who had absorbed a variety of influences—from his Jewish background, contemporary Europe, American folk music and jazz, Latin American music—while writing music which is instantly recognisable as his own in its clean textures and taut rhythms. Early works such as the Piano Concerto (1927) show the use of jazz styles, while the Piano Variations (1930) combine inventiveness and technical discipline in a tough, concentrated and highly dissonant piece. A move towards a simpler, more immediately appealing idiom is evident in pieces like *El Salón México* (1936), and the ballets *Billy the Kid* (1938), *Rodeo* (1938) and *Appalachian Spring* (1944) and the Third Symphony (1946). These works remain Copland's most popular and frequently performed pieces. A number of works from the 1950s and 1960s experiment with serial techniques, while retaining his individual voice. Also popular is his Fanfare for the Common Man.

Vaughan Williams, Holst and Delius.

The twentieth century revival of music in England owes much to Ralph Vaughan Williams (1872–1958) and Gustav Holst (1874-1934). The English folk song revival, associated with Cecil Sharp, was in full swing during their formative years, and both composers produced arrangements of folk songs as well as assimilating the folk idiom into their own styles. The influence of 16th century polyphony is also strong in Vaughan Williams' music, the most obvious example being the *Fantasia on a Theme by Thomas Tallis* (1909). Vaughan Williams' strongest works (*e.g.* the first, fourth, fifth and sixth symphonies, the ballet *Job*, the choral *Dona Nobis Pacem*) show his characteristic alternation of the forceful and the contemplative.

Holst was a more enigmatic figure. Only his suite *The Planets* and the choral work *The Hymn of Jesus* have established themselves in the regular repertory, but his bold harmonic experiments and the austerity, even mysticism, of his style as heard in the opera *Savitri* and the orchestral piece *Egdon Heath* are perhaps more typical of this composer.

Frederick Delius (1862–1934) was the major English composer to fall under the sway of French impressionism, though his English (north country) background, his friendship with Grieg, and the time he spent in America all contributed to the formation of his musical style. He lived in France from 1888 onwards. His most important works are the atmospheric tone-poems for orchestra, such as *Brigg Fair*, the vocal and orchestral *A Mass of Life*, *Sea Drift* and *Appalachia*, and the opera *A Village Romeo and Juliet.*

Sir William Walton.

Sir William Walton (1902–83) became known as an *enfant terrible* with the witty and irreverent *Facade* (1923) for speaker and chamber orchestra (with words by Edith Sitwell). The poetic Viola Concerto (1929) shows another side of his musical character. His First Symphony (1934-5) is an arresting, dramatic score and the colourful oratorio *Belshazzar's Feast* (1931) is a landmark in choral music. Walton's rhythms show the influence of jazz and of Stravinsky but he is generally felt to be a quintessentially English composer. An Elgarian element is clear in such occasional pieces as the coronation marches *Crown Imperial* (1937) and *Orb and Sceptre* (1953).

Benjamin Britten.

Benjamin Britten (1913–76) did as much as anyone to establish English music on the forefront of the international stage. Much of his music seems to have an immediate appeal to large audiences and certainly his many stage works earned him quite exceptional prestige both at home and abroad. *Peter Grimes* (1945), *Billy Budd* (1951), *Gloriana* (1953), *A Midsummer Night's Dream* (1960) all show his mastery of stage technique and the first two are also moving human documents. On a smaller scale he has achieved as much with his chamber operas—*The Rape of Lucretia* (1946), *Albert Herring* (1947), *The Turn of the Screw* (1954)—and the three Parables for Church Performance—*Curlew River* (1964), *The Burning Fiery Furnace* (1966) and *The Prodigal Son* (1968). His operatic output was crowned by *Death in Venice* (1973). If he had written nothing else, these dramatic works would have marked him out as a composer of outstanding imaginative gifts. In addition to these, however, the choral works culminating in the *War Requiem* (1962), the various song cycles written, like so much else, for his friend Peter Pears, the *Serenade* for tenor, horn and strings, *Nocturne* for tenor and orchestra, the three *Canticles*, and the *Spring Symphony* are further evidence of both his intense emotional commitment and his technical skill. Despite the strong influence of such composers as Purcell, Schubert, Verdi, Mahler and Berg, his style is entirely his own; his musical personality combines, it has been said, "a deep nostalgia for the innocence of childhood, a mercurial sense of humour and a passionate sympathy with the victims of prejudice and misunderstanding."

Sir Michael Tippett.

This last quality was also evident in the emotional make up of Sir Michael Tippett (1905–98), as expressed in such works as the oratorio *A Child of our Time* (1941) one of his earliest successes, which shows both his compassion and his ability to write on a large scale. This and the Concerto for Double String Orchestra (1939) remain his most popular works. Tippett was open to a wide range of influences, both musical (from English Madrigals, Monteverdi and Beethoven to Negro spirituals and jazz) and non-musical (*e.g.* the ideas of Jung). His early style—often richly lyrical and affirmative of the continued power of tonality—reached its culmination in his allegorical opera *The Midsummer Marriage* (1952), the Piano Concerto (1955) and the Second Symphony (1957). A new style, spare and incisive, with structure arising from the juxtaposition of contrasting ideas rather than from a process of development, was evident in his second opera, *King Priam* (1961) and its offshoots, the Second Piano Sonata (1962) and Concerto for Orchestra (1963).

The mystical, ecstatic *The Vision of St. Augustine* (1965), a complex, difficult but rewarding work, is one of his finest from this period. The opera *The Knot Garden* (1970) exemplifies again Tippett's concern with human relationships and the need for self-knowledge. Tippett never ceased to explore and experiment; his inspiration still seems as fresh as ever. His most recent works, *The Mask of Time*— a huge choral piece—and the Fourth Piano Sonata (1984) have something of the quality of summarising statements about the musical and non-musical concerns of a lifetime.

Olivier Messiaen.

Amongst the many schools and groups of composers in the twentieth century, two major figures stand apart, Olivier Messiaen (1908–92) and Elliott Carter. Both born in 1908, each is an individualist of great influence and stature who has pursued his own path to a personal style of composition.

A devout Catholic, Messiaen viewed himself as a theological composer and music as a medium for a profound communication, celebration and contemplation of the love and mystery of God. Few of his works are liturgical but most have religious and doctrinal themes, for example *La Nativité du Seigneur* (1935) for organ and *Vingt Regards sur l'Enfant-Jésus* (1944) for piano. Messiaen was inspired to compose by hearing the music of Debussy. This influence can be particularly seen in Messiaen's flexible rhythms, sensitive scoring and use of timbre. Indeed, he identifies sounds with colours and views composition as painting. The other major early influence was that of the East, particularly India.

Elements of Messiaen's Music.

Messiaen often uses Hindu rhythmic patterns alongside Greek poetic metres, plainsong and other medieval techniques and Stravinskian devices. The sum of these can be seen in *Quatuor pour la fin du temps* for violin, clarinet, cello and piano which he composed in a prisoner of war camp in 1940. A very complex work, it reflects the primacy Messiaen gives to rhythmic control. Its overwhelming impression however is of lush and exotic sounds and textures. Similarly, the vibrant colours and rhythms of the massive *Turangalila-symphonie* (1946–8) for orchestra effectively realise the ideas of life and vitality embodied in the Sanskrit title.

After *Turangalila*, Messiaen adopted a less luxurious style. It was works such as the *Livre d'orgue* (1951) which profoundly influenced many young composers of post-war years in the use of systematic transformations of rhythm and dynamics using a system of modes in a quasi-serial fashion. For Messiaen it is the seven harmonic modes, inspired by Debussy, Liszt and the Russian "Five", which are perhaps more important because they give his music its unique sound quality.

The 1950s saw the integration of the final element crucial to Messiaen's music; birdsong. A keen ornithologist, he collected and accurately notated the songs of many birds for incorporation into compositions. *Catalogue d'oiseaux* (1951–8) is a collection of thirteen piano pieces featuring French bird songs.

Messiaen after 1960.

Since 1960, his style has become less complex to the ear. To encounter the many elements of his music one can do little better than to listen to *La Transfiguration de Notre Seigneur Jésus-Christ* (1963–9) for one hundred voices, seven instrumental soloists and a large orchestra. Its subject is the mystery of God, his relationship with man and nature as a revelation of God. Messiaen draws upon all his compositional techniques in a spellbinding and overwhelming work that is a profound affirmation of faith. It is fitting that his opera (1973–83), *St François d'Assise* is about the saint who is best known for his great spirituality and for gaining inspiration and insight from nature. *Éclairs sur l'Au-delà* (1988–92) was Messiaen's final completed work and successfully explores much of his earlier musical elements.

Elliott Carter.

Elliott Carter (1908–2012) concentrated on problems of language and structure in a dramatic context unlike Messiaen's preoccupations with colour and the communication of religious truths. Carter's early works reflect a variety of influences: Stravinsky, Hindemith and the English Virginalists. He consciously aimed at a simple, lyrical, accessible style, for example, in the ballet, *Pocahontas* (1938–9) and *Holiday Overture* (1944). During those war years however there occurred a change of direction. The Piano Sonata (1945–6) saw the start of a compositional style where instruments were endowed with personalities who act as protagonists in a drama. His ideas crystallised in the *String Quartet No. 1* (1950– 1) after an absorbing study of the music of Ives, Cowell and African and Oriental music. It led to the use of very complex rhythmic relationships and a very tightly-knit pitch structure that could be traced back to a simple and small source, in this case a four-note chord. After this Carter refined his portrayal of his dramatis personae such that in *String Quartet No. 2* (1959) his players each have a separate personality defined by melodic material, gestures and rhythms. They converse, argue and enact that work's dramatic programme. *String Quartet No. 3* (1971) marked a shift in approach. Although the players were still "personalities", the work relied heavily on the use of contrast between strict and flexible writing between members of two duos. The *Symphony of Three Orchestras* (1975–7) and *Triple Duo* (1983) continue to explore the possibilities of simultaneous presentation of independent and sometimes unrelated processes.

The works of Carter's very productive final years, such as *Interventions* for piano and orchestra (2007), the song-cycle *A Sunbeam's Architecture* (2010) and *String Trio* (2011), demonstrate his continued compositional mastery and invention.

The Avant Garde since 1945.

The early post-war years saw a renewed interest in "twelve-note techniques" otherwise known as "serialism". Composers like Stravinsky and Dallapiccola (1904–75), who had shunned serialism in earlier years, began to experiment and absorb serial techniques into their musical style. Stravinsky, for example, in works such as *Threni* (1957–8) explored ideas of varied repetition both of small ideas and large sections, in a serial context. A clear example to listen to is the fifteen-minute *Requiem Canticles* (1964–6). During the progression from its Prelude to Postlude, one can hear the piece subtly develop. The succeeding movements, and phrases within movements, slightly alter that which has gone before, evolving into something fresh.

Serialism.

This period also saw the emergence of a new generation of composers, keen to jettison the past and begin anew. Serialism was a favoured tool, its revival stemming from Paris, where Webern's pupil René Leibowitz was teaching, and the USA where Schoenberg had fled from Nazi Germany. The American Milton Babbitt (1916–2011) was much concerned with codifying serial techniques. His younger European counterparts Pierre Boulez (1925-2016) and Karlheinz Stockhausen (1928–2007) sought to increase the number of musical elements that could be controlled by a predetermined method. They sought to emulate the rigorous methods of Webern, hoping to control not only pitch, but also rhythm, timbre *etc*. In doing so they hoped to create an impersonal, emotionally restrained music.

Attention went first to controlling rhythm. Forerunners of this control can be seen in movement three of Berg's *Lyric Suite* and in Webern's Op.30 Variations. However, the catalyst came from Messiaen. He inspired his pupil Boulez to explore the possibilities of rhythmic and dynamic serialism in his Second Piano Sonata (1951). The performance of Messiaen's *Modes de valeurs et d'intensités* (1949) at the Darmstadt Summer School proved decisive for Stockhausen. Although not serial, the piece established scales of pitch, length of note (duration), loudness and attack. The 1950s were to see this potential for serialism taken to extremes. Boulez reached "total serialism" in *Structures 1a* for piano. However, having attained it he soon became frustrated with its restrictions. Some of the more fantastic and exotic elements of earlier works were allowed to reappear. *Le Marteau sans Maître* (1952–4) for mezzo-soprano and six instruments is a masterly setting of three surreal poems by René Char, with instrumental interludes. It is the contrasts of timbres, of flexible and regular pulsing rhythms, of sound and silence that are spellbinding. The virtuosic serial workings are hidden.

The Achievement of Total Serialism.

Stockhausen reached total serialism in *Kreuzspiel* (1951) for oboe, bass clarinet, piano and percussion. Each note's pitch, length, dynamic and timbre are part of a predetermined plan. All are concerned with "Kreuzspiel" or "crossplay". Its various processes reverse or change over throughout so that at the end we have returned full circle. The effect is of clear-cut lines where each note is weighted. However, despite the intention of the composer, the effect is not unemotional, especially with the insistent throbbing of the percussion, and the piece builds to a series of climaxes before dying away. *Punkte* (points) (1952) for orchestra finds each note being treated as an isolated point of sound. It illustrates some of the problems of total serialism; often very difficult to play, it can be monotonous or lack focal points, appearing to be random rather than rigorously controlled. Stockhausen therefore transferred his attention to using not points but bursts of sound and moved towards possibly his most significant contribution to music, "moment form". There, different aspects of a note, chord or sound are suspended in eternity for contemplation and re-examination. Works became longer, slower and had a greater emphasis on colour and the effects of spatial separation, both between sounds and between their sources. *Carré* (1959–60) uses four orchestras between which chords move and evolve.

Although unifying principles in pitch content *etc.* might be present, "strict" serialism had been gently left behind, until *Mantra* (1970). This work for two pianos, percussion and two electronic ring modulators is totally based on a thirteen-note row, the mantra, with a different duration, mode of attack and dynamic for each note. These permeate the whole piece. For example, each of the thirteen sections is dominated by one of the thirteen types of attack. The work's climax is the coda where the 156 versions of the mantra used are rushed through in a few minutes. The work is important, not only as marking a return to serialism and notated music, but also in its rediscovery of melody.

Later Serialism.

Since the 1960s serialism and integral serialism have had less of an influence in Europe, although they continued to hold a fascination for American composers such as Milton Babbit (1916–2011). Composers have used the underlying concept of serialism (*i.e.* using a systematic approach to detailed structuring) without using the technique in any strict sense. Examples of this include Maxwell Davies's use of magic number squares (*see below*), and Harrison Birtwistle's use of random numbers to generate rhythmic and melodic elements. The Hungarian composer György Ligeti (1923–2006) used very tightly controlled canonic music which he described as 'micropolyphony' which, though not serial, has a similarly organised and systematic approach. One of the reasons for the use of systems is to take some of the decision-making out of the compositional process. Birtwistle has said that he would seize up if he had to make all the decisions!

Mathematics and Music.

The younger generation of composers often used mathematical systems in composing which were not necessarily serial. A good example was Sir Peter Maxwell Davies (1934-2016). The use of durational ratios, ciphers and magic squares features prominently in his work, partly reflecting his interest in medieval music. A magic square is a number square where the sum of any line is the same. This becomes the basis for a composition by assigning notes to the numbers—a technique that Davies often used after the mid-1970s. For example, in *Ave Maris Stella* (1975), each of the nine movements uses a different transformation of the square and follows a characteristic route through the square. The work is governed by the square at all levels: it even determines the precise length of each movement. Far from being a mathematical exercise however the piece shows masterly control which is particularly revealed in its drama and the beauty of its colours.

Mathematical processes of a different type were taken up by the Greek, Xenakis (1922–2001), possibly because of his original training as an engineer and architect in France. His rejection of serialism led to the use of "stochastic" principles, derived from the mathematical laws governing probability. He also applied mathematical set theory to composition. The use of these ideas however is not audible. In *Nomos Alpha* (1965) for solo cello, for example, it is the use of contrasts, texture *etc.*, which give shape and form for the listener.

Eastern Influences.

Although for many serialism represented the way of reviving music after the excesses of romanticism, some looked beyond Europe to the East. John Cage (1912–92) found inspiration there, studying Zen Buddhism in the early 1950s. By using the "chance operations" of the Chinese *I Ching* (Book of Changes) Cage brought a new radical approach to Western music. *Music of Changes* (1951) for piano is fully notated but its content is the result of operations where chance has a role. The use of "indeterminacy" or "chance" gave the performer an active role in determining the course of a piece. This might come about by providing "graphic notation"—an artist's impression of what the piece might sound like. Thus Earle Brown's *December 1952* is a visual design to be realised on any instrument as the performer sees fit. Alternatively the composer could give the performer control over the order of sections or their content. *Twenty-five pages* (1953) by Brown is for one to twenty-five pianos. Each person has twenty-five pages and may arrange them in any order before commencing. Thus music was no longer to be necessarily a progression of fixed and immutable steps to an endpoint. This and other traditional assumptions about music were challenged in Cage's most well-known outrage, *4′ 33″*. The performer does not play any notes at all. The music consists of the sounds in the environment that occur during a period of four minutes and thirty-three seconds.

Chance and Indeterminacy.

In 1957, both Stockhausen and Boulez took to chance having realised that total control was an impossibility. The more rigorous the control of musical elements, the more impossible it became to realise it accurately. Stockhausen's first experiment with chance techniques was Piano Piece XI which is a single page with nineteen fragments of music. They may be played in any order but the tempo, dynamic and attack must be that shown at the end of the previous fragment. After one fragment has been played three times the work ends. Boulez's Third Piano Sonata was less free. There the choices are in the nature of varying routes through the piece. Boulez saw his music as using a form of control that is not random but akin to throwing a dice. Limited choices in the combination of instruments and their choice of lines form the basis of *Pli selon pli* (1957–65) for soprano and orchestra, offering Boulez a way "to fix the infinite".

For Stockhausen, chance has been a way to encourage performer participation and the development of "intuitive music-making". In *Prozession* (1967) for example, performers react to what is going on guided by plus or minus signs in the score which denote whether the response should be positive or negative. It has worked well in combination with the ideas behind moment form. *Stimmung* (1968) is a 45 minute meditation on one chord whose parts and overtones emerge and merge into the whole, punctuated by erotic poems, magic numbers and words which are delivered in response to chance operations. The climax of these ideas may be seen in *Aus den Sieben Tagen* (1968) where the score for each of the seven movements is a short poem.

Witold Lutoslawski.

Use of indeterminacy does not necessarily have to be so extreme. For Witold Lutoslawski (1913–93) use of controlled chance techniques has provided a way for composing atonal music without embracing serialism. During 1955-60 Lutoslawski evolved a harmonic language which used twelve-note chords for expression and colour. In 1960 he heard a performance of Cage's Piano Concerto and realised that he could use chance techniques to add a rhythmic freedom and new types of texture to his music. The exact combination of sounds at any given moment is often a matter of chance but the overall effect is planned. Textures are created by the constant repetition of small melodic ideas and simple rhythms in different parts, creating a kaleidoscope of sound, and by lines of counterpoint set off against each other, often sliding from one note to another blurring the transition between chords. The music of Lutoslawski is a fine example of the use of chance as a tool in compositions which still have strong links to tradition. The direction and drama of works such as *Mi-Parti* (1976) and his Third Symphony (1983) are firmly in the composer's hands, relying heavily on his skilful sense of harmonic movement, use of colour and proportion. Only small rhythmic details are left to chance.

The Music of Ligeti.

Ligeti's music often sounds as if it were chance-like but in fact his massive textural structures of the 1960s are controlled by highly organised arhythmic canons. Each instrument or voice follows the same line of notes but with different rhythmic values. The listener hears a kaleidoscopic and ever-changing background cluster. Works from this period include: *Atmosphères* for orchestra (1961), *Requiem* (1963-5), and *Lux Aeterna* for voices (1966).

Ligeti's music was made famous when the above works were used (without the composer's permission) by Stanley Kubrick in his film *2001: a Space Odyssey*. Ligeti's music since the 1970s shows a rediscovery of elements that he had previously shunned such as melody, harmony and even tonality/modality. Typical examples include Horn Trio (1982), Piano Concerto (1988) and Violin Concerto (1992) which show influences from African music, fractal geometry and the piano music of the American Conlon Nancarrow (1912–97). The rediscovery of previously rejected elements can also be seen in the music of the Polish composer Krzysztof Penderecki (b. 1933) and Luciano Berio (1925-2003), and can be seen as a symptom of the existence of Post-Modernism in music.

The Advent of Electronic Music.

An important part of the post-war struggle with musical language has been the development of electronic means to generate, manipulate and record sounds. Its pioneer was the Frenchman Edgard Varèse (1883–1965). Before the war he had been an independent and radical composer much concerned with the exploration of new sounds. This had led to an emphasis on the exploitation of percussion effects in works such as *Intégrales* (1924–5) and *Ionisation* (1933). The following work *Ecuatorial* (1934) explored further, using primitive electrically generated sounds produced by two Ondes Martenot. However the catalyst for further development was the invention of the tape recorder which provided an easy means to store sounds that could then be rearranged by cutting and rejoining the tape in different ways. Varèse explored these possibilities in *Déserts* (1949-54) which alternated recorded and instrumental sounds in an atmospheric work which really seems to conjure up the aridity and emptiness of the desert. Recorded sound offered the possibility of creating illusions of aural space by technical manipulation and by judicious positioning and control of loudspeakers. This is a fundamental part of Varèse's great masterpiece, *Poème Electronique* (1958) which used soprano, chorus, bells, organs and artificial sounds. Its spatial effects were achieved by using many loudspeakers positioned around a specially designed pavilion at the 1958 Brussels Exhibition.

Generally, electronic music-making required a studio and the 1950s saw the setting up of important studios in Paris and Cologne. In Paris Pierre Schaeffer (1910-95) pioneered "*musique concrète*" which used altered and rearranged natural sounds, for example, the sound of a steam train, to create a musical piece. At Cologne where Stockhausen worked, the emphasis was on new synthetic sounds.

The Potential of Electronic Music.

Electronic music had the potential to generate complex, accurate serial structures through precise electronic operations. Boulez's studies in this however did not satisfy him and he neglected the medium until 1970 when he became Director of IRCAM (*Institut de Recherche et de Coordination Acoustique/Musique*). Stockhausen however found electronic music an ideal medium to create a musical unity far beyond that of serialism; pitch, timbre, rhythm and form could be seen as different aspects of the same thing—vibration. He did not restrict himself to pure synthetic sounds and in 1955–6 created perhaps his most well-known electronic work, *Gesang der Jünglinge*.

With *Kontakte* (1958–60) for piano, percussion and tape, Stockhausen began an exploration of the interplay between live performers and electronic sound which still preoccupies him today. The work explores "contact" between real and artificial sounds and between the elements of music. Compared to pure electronic music, the presence of the live performers made it easier to listen to, providing a visual focus and making each performance unique. The next step was to create "live" electronic music where performers created their electronic sounds on stage. Cage had already begun this in 1960 with *Cartridge Music*. Unlike Stockhausen's first attempt, *Mikrophonie I* (1964–5), *Cartridge Music* gives much freedom to the performer in creating the electronic effects. A desire to create a world music led to one of the most vast electronic works to date, *Hymnen* (1966–7), a two-hour work for quadraphonic tape or tapes, soloists and optional symphony orchestra. Stockhausen constructed it out of national anthems from all over the world. Inspired by the occult *Urantia Book*, he became more ambitious still, seeking a galactic music. *Sirius* (1977) for four soloists and electronic music deals with the arrival on earth of four visitors from the star Sirius.

Electronic Music in America.

In America, developments have followed a different course. There, the use of computer synthesised sounds has been the main interest because of the computer's superior control and accuracy. It has allowed the continuation of abstract composition where complicated operations are achieved simply and effectively.

Minimalism.

The transformation of existing material on tape has been a crucial part of an American movement dating from the 1960s known as "Minimalism'. Its chief exponents are Steve Reich (b. 1936), Philip Glass (b. 1937), Terry Riley (b. 1935), La Monte Young (b. 1935) and John Adams (b. 1947). Minimal music uses material which is limited in pitch, rhythm and timbres; the elements are subjected to simple transformations relying heavily on repetition. Of great importance are the subtle evolution from one idea to another as repetitions are modified, and the use of "phasing" techniques. Phasing is the effect of altering the rate of repetition between parts repeating the same material so that it is no longer synchronised. The effect of works such as *Drumming* (1971) by Reich may appear long and non-dramatic. However, the listener is not expected to concentrate all the time but to become aware of a piece's various elements and processes. The music's patterns will change as the listener's attention shifts from one aspect to another. As in moment form, minimalist works owe much to Indian concepts of time as a circular rather than linear phenomenon. In recent years, the minimalists have developed their style and there are greater differences between the four. Glass has written several operas including *Einstein on the Beach* (1975), *Satyagraha* (1980), *Akhenaten* (1983), *The Voyage* (1992) and *Galileo Galilei* (2001).

Reich's other works include *The Four Sections* (1987) for orchestra, *The Cave* (1993), a multimedia extravaganza, and *WTC 9/11* (2011), commissioned by the Kronos Quartet for the 10th anniversary of the attacks on the World Trade Center.

Music Theatre.

During the early post-war years many composers were grappling with the tools of composition. Only more "traditional" writers such as Britten, Tippett and Hans Werner Henze (1926–2012) were engaged in writing opera. By 1970 however, most composers were including elements of theatre in their work.

One of the major composers of "traditional" opera was Henze. His first three operas draw heavily on the past. For example, *Boulevard Solitude* (1952) updates the story of Manon, a nineteenth-century favourite. After moving to Italy in 1953, Henze's stance appeared more traditional still as lyrical elements became more dominant in contrast to the abstract athematic style of contemporaries such as Stockhausen. Increasingly Henze's operas began to reflect his preoccupation with socialism. The *Bassarids* (1966), for example, examines through a mythological guise the precipitation of social upheaval and disruption. The oratorio *Das Floss der "Medusa"* (1968) is dedicated to Che Guevara and provoked such struggles between police and left-wing students at its premiere that Henze went to Cuba for a year. There he was inspired to write *El Cimarrón* (1969–70), a vocal monologue portraying a Cuban runaway slave accompanied by flute, guitar and percussion. For a while, Henze continued to reject the traditional opera format because of its bourgeois overtones, preferring a more intimate, chamber style. But in 1976 Henze returned to opera with *We come to the River*. It reflected a renewal of Italianate lyricism, the exploitation of opera's full potential and a less overt political message.

Exponents of Music Theatre.

Luigi Nono (1924–90) also exploited theatre for political ends, beginning with *Intolleranza* (1960). However he found greater resource than Henze in contemporary developments, taking full advantage of the opportunities offered by electronics. *Contrappunto dialettico della mente* (1967–8) includes the sounds of political demonstrations. Like Henze, Nono also returned to the opera house after a long break from large-scale opera with *Al gran sole carico d'amore* (1972–4), which consolidated the techniques he had developed in the previous decade.

"Theatre" was a dominant characteristic in the works of Luciano Berio (1925–2003). One of his most famous works is *Circles* (1960) for female voice, harp and percussion. The virtuosic technique used there and in other works was inspired by the phenomenal vocal elasticity of his then wife, Cathy Berberian. "Circles' are depicted at many different levels in the work's structure and content. More importantly, these are underlined by the singer moving about the stage during the performance.

Berio's next few works became overtly political, culminating in *Laborintus II* (1965) which was intended as an attack on capitalism via a musical collage and extracts from Dante's *Inferno*. Many of Berio's larger scale works since *Laborintus II* have been theatrical in their virtuosity and instrumental technique. For example, *Sequenza IV* (1965) demands a pianist with very agile feet. This type of dramatic gesture is much seen in Stockhausen's work, particularly those written for his own music ensemble, for example, *Solo* (1966). Since *Alphabet für Liege* (1972) his work became increasingly theatrical and from 1978 Stockhausen spent the latter part of his life writing *Licht* (1977–2003), the opera cycle based on the seven days of the week.

Influences on Other Composers.

The small-scale synthesis of text, music and gesture characteristic of Berio greatly influenced British work in music theatre, notably the work of Sir Peter Maxwell Davies and Sir Harrison Birtwistle. Davies' work was very powerful particularly through its use of parody and wild use of outrageous gesture. *Vesalii Icones* (1969) used a naked male dancer portraying parts of the Stations of the Cross and scenes from the anatomy text by Vesalius. It is a good example of parody, particularly of what Davies saw as nineteenth-century grossness—it includes a vile distortion of a Victorian hymn tune which turns into a foxtrot, both played on a honky-tonk piano. Many of his works feature a single vocal soloist, with instrumental back-up, who plays the part of a crazed, obsessive individual. For example, *Eight Songs for a Mad King* (1969) features the instrumentalists in giant bird cages who must suffer the mad ravings of George III played by the singer.

Davies wrote three full-scale operas: *Taverner* (1962–8), *The Martyrdom of St. Magnus* (1976) and *Resurrection* (1987). *Taverner* deals with two fundamental preoccupations of Davies—the nature of faith and betrayal—and uses both musical and dramatic parody to convey its message. *St. Magnus* was written after Davies moved to Orkney. It reflects a change in style, uses only a small orchestra and is for production "in the round". Latterly Maxwell Davies explored the traditional orchestral sound world, through the composition of 10 symphonies which were strongly influenced by Sibelius. From 2004 to 2014 he was Master of the Queen's Musick. Created Companion of Honour (2014). He died in 2016.

Birtwistle's first major dramatic work was a chamber opera, *Punch and Judy* (1966) which uses grotesque and violent gestures. However, while Davies' roots may lie with early Schoenberg, Birtwistle has found inspiration in the clear-cut lines and ritualism of Stravinsky. Possibly his most significant work to date is *The Mask of Orpheus* (1973–5 and 1981–3). He has written a further four operas: *Gawain* (1981–91); *The Second Mrs. Kong* (1994), *The Last Supper* (2000) and *The Minotaur* (2008). He was made a Companion of Honour in 2001.

Music of the Late Twentieth Century.

Brian Ferneyhough (b. 1943) is continuing to expand the chamber music repertoire using traditional structures as a framework for music in which micro-tones play an increasingly important part. A significant part of his output before 1990 is the group of seven compositions, *Carceri d'invenzione* (1981–6), 'dungeons of invention' referring to the etchings of Piranesi. He has become the focus of a style of composition named 'the New Complexity' which pushes the techniques of players to their limits and creates extremely complex textures. His recent work includes his 6th String Quartet (2010).

Robin Holloway (b. 1943) has written a number of works taking music by earlier composers as a starting-point, *e.g. Scenes from Schumann* (1970) for orchestra, *Gilded Goldbergs* (1992–7, after Bach) for two pianos. Nigel Osborne (b. 1948) has used electronic and non-Western music in his work, gravitating recently towards vocal works. 1986 saw the premiere of his theatre piece, *Hells Angels*. Other recent operas are *Where the Wild Things Are* (1984) and *Higglety, Pigglety Pop!* (1985) by Oliver Knussen (b. 1952) which attracted acclaim for a young composer already noted for his symphonies, vocal and chamber work. Tim Souster (1943–94) was active in composing and promoting electronic music of all types, some influenced by rock music. A good example is his *Quartet with Tape* (1985).

George Benjamin (b. 1960) won fame early with *Ringed by the Flat Horizon* (1980); a recent work is the opera *Written on Skin* (2012).

Diversity of Approach.

The British composers who emerged in the 1980s and 1990s were diverse in their compositional approaches and interests. One feature they do have in common is an eclecticism drawing from a wide range of sources such as football chants (Turnage), jazz (Butler) and Celtic culture (MacMillan and Weir). There has also been a trend towards greater approachability in the style and language of their music. There has been a realisation that audiences have been alienated in the past, and composers have attempted to make their music more communicative. One manifestation of this is the apparent 'rediscovery' of tonality or modality.

Some Late Twentieth Century British Composers.

Mark-Anthony Turnage (b. 1960) is one of the most characteristic and popular composers of his generation. He uses material from popular culture in his music (like Martland and MacMillan) including rhythmic and melodic elements, which can be most clearly seen in his controversial opera *Greek* (1990), a setting of Steven Berkoff's play. His rich and colourful orchestration can be heard in his orchestral works such as *Three Screaming Popes* (1989), *Momentum* (1990–1), *Drowned Out* (1993) and his highly successful opera *The Silver Tassie* (1997–9). Recent major works are the opera *Anna Nicole* (2011) and the orchestral *Frieze* (2013), composed as a response to Beethoven's 9th Symphony. Awarded CBE in 2015.

James MacMillan (b. 1959) is a part of the general rebirth of the arts in Scotland and shows something of his Celtic heritage in such works as *The Confessions of Isobel Gowrie* (1990) which explores a wide range of Scottish traditional music. His music since *Litanies of Iron and Stone* (1987) shows an increase in rhythmic drive, perhaps influenced by his interest in rock music, and also an increasing approachability. His major compositions since *Litanies* have mostly used external political or religious subjects as inspiration, for example *The Exorcism of Rio Sumpul* (1989) which is based on a helicopter raid on a village in El Salvador. His musical language is characterised by colourful instrumentation, a powerful rhythmic drive and an eloquent lyricism, which can be seen clearly in his popular *Veni Veni Emmanuel* (1993) written for the percussionist Evelyn Glennie. His first full-scale opera was *Ines de Castro* (1995). His Catholic faith has inspired works such as the *St John Passion* (2007) and *Credo* (2012). He became involved in setting up a music festival in Cumnock, Ayrshire.

Judith Weir (b. 1954) also makes reference to her Celtic heritage in her music. Her main compositional output is in the area of opera and music drama. *A Night at the Chinese Opera* (1987) is perhaps her best known work to date and is evidence of her interest in Chinese Yuan dramas. Her two later operas use magical stories: *The Vanishing Bridegroom* (1990) is based on 3 linked Scottish folktales, and *Blond Eckbert* (1994, for the English National Opera) on a fairytale by the German Romantic writer Ludwig Tieck. Her musical language shows influences from folk music, tonality and composers such as Stravinsky, Janáček and Peter Maxwell Davies.

Her latest large-scale works are *Concrete* (2007), written for the BBC Symphony Orchestra and Chorus, a kind of musical history of London, and the opera *Miss Fortune* (2011). She was appointed Master of the Queen's Musick in 2014.

Martin Butler (b. 1960) like MacMillan has shown a shift in his musical language from a Modernist approach to one which is more eclectic and expressive. As he states: "Recent pieces of mine have drawn, more or less directly, on Irish and bluegrass fiddle music, Latin salsa and dance music, and various types of jazz." Examples showing these influences include *Jazz Machines* (1990) for chamber ensemble, *Bluegrass Variations* (1988) for violin, and *Tin Pan Ballet* (1986) for ensemble and DX7 synthesiser. One of his most distinctive works is his opera *Craig's Progress* (1994) which uses the "twin inheritances of opera and comic books". *Préludes Inégales* for piano (2013) combines improvised and fully composed elements. Other recent works include *Rondes d'automne* (2011) for wind and strings.

Steve Martland (1959-2013) was a key figure of radical minimalism and owed much of his musical development to his studies with Louis Andriessen at the Royal Conservatory in The Hague. His music, like that of MacMillan, was strongly shaped by his socialist politics and was characterised by uncompromising aggression and bold sonorities. Like Andriessen he explored hocketing techniques in works like *Drill* (1987) and *Birthday Hocket* (1989), both for 2 pianos. His larger scale works include *Babi Yar* (1983) for large orchestra in 3 groups and *Crossing the Border* (1990–91) for String Orchestra. Later works are *Darwin* (2009) for choir, brass quintet and organ, setting extracts from Darwin's *Origin of Species* alongside a letter from Darwin's wife Emma; *Sea Songs* (2011) for choir; and *Beat the Retreat* (2012) for 11 players.

Thomas Adès (b. 1971) is one of the most distinctive and accomplished British composers of a younger generation. He made a swift rise to prominence through his beautifully crafted works such as *Asyla* (1997), the Chamber Symphony (1990) and his first chamber opera: *Powder Her Face* (1995), based on the life of the notorious Duchess of Argyll. His works show traces of the textural music of Ligeti but also reference jazz and popular music to create an approachable but highly wrought musical language. His largest and most ambitious work to date is his opera *The Tempest* (2003–4) based on Shakespeare's play which was commissioned by the Royal Opera House.

Recent works include *Polaris* (2010) for orchestra (plus moving images on 5 video screens), *Totentanz* (2013) for mezzo-soprano, baritone and orchestra and *The Exterminating Angel* (2016).

Prospect and Retrospect.

The major shift in contemporary music over the last 30 years has been towards a more tonal/modal music with a parallel shift towards greater comprehensibility. It is likely that successful composers in the future will be those who communicate directly with their audience. Some of the British composers discussed earlier, such as Weir and Turnage, show this characteristic, although this is not to suggest that their music is without depth or richness.

There has also been a continued interest of composers into popular idioms and an exploration of the grey areas in between genres. Minimalism and Post-Minimalism, which explore the interesting area of contemporary music, popular music and world music, continue to thrive and evolve into more sophisticated and varied forms. It would be wrong to suggest that the tougher, more modernist style of music will disappear over the coming years, diversity of style and pluralism will continue to be a defining characteristic of New Music. Some of the most innovative current composers and stylistic groupings are outlined below.

Popular Minimalism: Michael Nyman.

The British composer Michael Nyman (b. 1944) is an example of a composer who writes music which cannot be easily categorised, as it consists of an amalgam of Minimalism, Baroque Ground Bass and Popular rhythms. Nyman's most characteristic works have been those written for Peter Greenaway's films such as *The Draughtsman's Contract* (1982), *A Zed and Two Noughts* (1985) and *The Cook, The Thief, His Wife, and Her Lover* (1989) which show a powerful and distinctive style. Nyman's music for *The Piano* (1992), directed by Jane Campion, is less hard-edged and original than his earlier works, but it does suit the film and has brought him much popularity. Non-film music includes; the chamber opera *The Man Who Mistook His Wife for a Hat* (1987) based on the case-study by psychiatrist Oliver Sacks and the music of Schumann; a Piano Concerto (1993) based on music from *The Piano;* five string quartets (1985, 1988, 1990, 1995 & 2011); and *I Sonetti Lussuriosi* (2007) for soprano and orchestra on erotic texts by the Renaissance poet Pietro Aretino. A recent substantial work is *Through the Only Window* (2012) for string quartet and piano. In 2014, as a memorial to the Hillsborough victims, he wrote *Symphony No. 11: Memorial.*

Post-Minimalism: John Adams.

The American composer John Adams is considered to be a significant innovator in the Minimalist genre. His recent style could be better classified as Post-Modernist or perhaps Post-Minimalist as he avoids the austere Minimalism of Steve Reich or Philip Glass, in favour of a richer and more backward looking style. *Grand Pianola Music* (1981) for chamber orchestra, 3 sopranos and 2 solo pianos is an example of this more eclectic approach using jazz-like harmony and a banal tune at the end which is very reminiscent of Beethoven's *Ode to Joy.*

Adams, like Glass, has latterly explored the larger canvas of opera using relatively recent historical events for the plots. Examples include: *Nixon in China* (1987) which outlines the historic meeting between President Nixon and Chairman Mao; and *The Death of Klinghoffer* (1991) which highlights the eternal clash of the Arabs and the Jews. What Adams's music shows above all is the increasing pluralism in the styles of contemporary music which include popular idioms and also the raiding of past musical genres to create a fascinating blend of disparate materials. His range is evident in the recent oratorio *The Gospel According to the Other Mary* (2012) and the Saxophone Concerto (2013).

The Modernists: Birtwistle, Stockhausen, Boulez.

Modernist composers, who reject the notion that there are 'easy answers' in art, will continue to have a significant role in contemporary music. The leading 'Modernists' include Stockhausen, Boulez, Birtwistle, Xenakis, Ligeti, and Ferneyhough. Their music is very diverse in style but they have a common commitment to atonal music, the use of systems in their music and an avoidance of the approachability of the Post-Modernists such as Holloway or the American David Del Tredici (b. 1937), or the Mystics such as Pärt, Tavener or Górecki.

Harrison Birtwistle is a British composer who has continued to use an uncompromising, non-tonal and often very aggressive musical language. He is also a figure who is seen as the most original and distinctive voice of his generation. His musical development can be seen as the gradual evolution of one basic approach which shows increasing refinement of technique, but without changing his main focus on the issue of the structuring of time. In addition to the operas mentioned above, significant works include: *Earth Dances* for large orchestra (1985–6), which shows a complex layering of strata, like the earth's crust; *Pulse Shadows* for soprano and string quartet (1989 96), including settings of poems by Paul Celan; *The Shadow of Night* for orchestra (2001); and a Violin Concerto (2009–10). A more recent choral work is *The Moth Requiem*.

In the 1995 last night of the Proms, John Drummond, the controller of Radio 3, had the audacity to commission Birtwistle to write *Panic* for John Harle, the saxophonist. The result was a wild and virtuoso work which sounds almost like free jazz. It caused uproar as it brought an example of modernist violence into what is usually a cosy, musically mediocre and blatant jingoistic event.

Other Modernists have perhaps fared less well in recent decades. Boulez, the archetypal Modernist, appeared to be rewriting old works such as the orchestral *Notations* (1977–) or continuations of existing works.

Stockhausen continued with his seven opera project *Licht* which he began in 1977 and completed in 2003, but he became increasingly isolated, working with a very close-knit group of players, including several of his family members. All his compositional work was focused on *Licht* which has much in common with Wagner's *The Ring* – however *Licht* seems to lack the unity and perhaps the consistency of *The Ring*. It seemed that Stockhausen was no longer the innovator of earlier years, and had perhaps lost his direction.

Mystics and the New Simplicity: Arvo Pärt.

As part of the shift towards a greater comprehensibility in music, a number of composers have written music imbued with mysticism, usually allied to an increased religious devotion. Arvo Pärt (b. 1935), the Estonian, is an example of a composer whose earlier works are in the Modernist serial tradition but who had a change of heart in the late 1960s. At this time he made an intensive study of Gregorian Chant, 13th century Notre Dame Organum, and Renaissance Polyphony.

He managed to incur the wrath of the old communist authorities throughout his career, firstly as a serial composer, then as a composer using religious texts, and finally, when Western Serialism was becoming accepted in the 1970s, he shifted to a new simplicity in his music. His most significant works in the later style include: *Tabula Rasa*, a double concerto for two violins (1977); *Passio* for voices and instruments (1982); *Stabat Mater* for soprano, alto and strings (1985); *Litany* for soloists, choir and orchestra (1994); and Symphony No.4 (2008).

Some Other Composers.

Other composers who have embraced a mystical and simple approach in their music include: Sir John Tavener the British composer of Eastern Orthodox faith; Henryk Górecki (1933–2010), the Polish composer whose Symphony No. 3 (1976) was a chart hit; and the Georgian symphonic composer Giya Kancheli (b. 1935). A forerunner of this approach was the prolific Armenian-American composer Alan Hovhaness (1911-2000).

Popular Music and Jazz.

The evolution of popular music and jazz is arguably the most far-reaching musical development of recent times. Many of the world's population have heard of Michael Jackson, or The Beatles, but few will have heard of such significant musical figures as Arnold Schönberg or Pierre Boulez. The audience for contemporary classical or 'art' music is an ever-shrinking one, and only styles which have links with popular music, such as minimalism, or look to the past, such as post-Modernist/neo-Romantic music, have any significant audience. Therefore popular music could be considered by future musicologists as the most significant musical genre of the twentieth century.

The term 'popular music' is problematic as not all popular music is actually that popular or commercial, but it has come to mean music which has its roots in the blues. Popular music is aimed at the whole spectrum of the population, whereas classical or 'art' music has always had a following among the educated middle classes, and therefore could be considered elitist.

The roots of present day popular music include folk song, African music, ballads, blues, jazz, and ragtime as well as elements of Western classical music. The development of blues, jazz and popular music will be outlined below.

The Blues: Origins.

The origins of the blues are a mixture of African influences brought by the slaves to North America, work songs used on the plantations, and Western musical elements. The work songs were sung by the slaves as they worked and had a call and response pattern. One man would sing the verse and the rest of the workers would reply with a chorus. The style of singing was different from the Western approach as it included growls, cries, and falsetto avoiding a pure tone. Rhythm is also a more developed feature in African music and the blues and jazz reflect this.

The field holler was a variety of work song which was sung by a lone worker and consisted of a long, tremulous one or two line call, often in falsetto, and comparatively free in form. This type of call has been recorded in the savannah parts of West Africa.

Other elements contributing to the origins of the blues include reels, dances, and jigs of Anglo-Scottish-Irish origin with African rhythmic elements and tuning, played on banjos (a descendant of the African *bania*) and fiddles. European-influenced song forms were also adopted by the Black Americans in the nineteenth century.

The Structure of the Blues.

The structure of the blues may have been heavily influenced by ballads such as *Railroad Bill* which was popular among black vocalists of the nineteenth century. This had the form of a couplet with a rhyming third line as a chorus. In blues the couplet was replaced with a repeated line:

See, see rider, see what you have done,
See, see rider, see what you have done,
You've made me love you, now my man done come.

The basic blues structure consisted of three lines within a 12 bar stanza and the rhyme schemes included *aaa*, *abb*, *abc* but *aab* predominated. The chord sequence, which was usually played by the guitar, can be described as follows (one chord per bar in the key of C major):

I (CEG), I, I, I, IV (FAC), IV, I, I, V^7 (GBDF),
IV, I, V^7 (last line I).

This is the most simple form and there are many variants.

The scale used by blues vocalists and instrumentalists is called the blues scale, because of the flattened or 'blue' notes. In the key of C major, the simplest scale consists of C E$^\flat$ F G B$^\flat$ which is also a pentatonic scale found in much folk music. The 'blue' notes are the E$^\flat$ and B$^\flat$ although a vocalist may not bend the notes exactly to these pitches.

The rhythmic language of the blues is also significant and includes syncopation; a displacement of the beat, and 'swung' quavers, consisting of the first quaver of a pair being longer and heavier than the second, rather than being equal as in classical music. Many of the above technical features, such as the 12 bar blues sequence, the blues scale, and the rhythmic style, can be observed in jazz and popular music.

Early Blues Singers.

The term 'blues' relating to song probably did not emerge until after 1900, but the original sixteenth century meaning was 'a condition of melancholy or depression' which describes the nature of many blues lyrics. The early blues singers, based in the South of the United States, worked in 'medicine shows' to attract buyers for dubious patent medicines. Wandering blues singers, rather like the French medieval troubadours, sang and played for their living, and helped to disseminate the blues in the early years of the present century. By 1910 white folk song collectors had noted the existence of the blues and in 1912 *Dallas Blues* by Hart Wand and Lloyd Garret was published – the first published example.

It is unlikely that the large number of published blues songs had a major effect on blues singers as few could read music. Probably the blues were passed on orally, and later, through recordings. The blues originated in the South, known as the Delta Blues, but in the 1920s blues singers moved North to record, along with the jazz musicians.

Classic Blues.

Mamie Smith (1883–1946) was the first black singer whose records were sold to the black public. *Crazy Blues*, which was recorded in 1920 and sold 75,000 copies in one month, made her a fortune and encouraged other black singers to follow her example, recording specifically for black listeners on what were dubbed 'race records'.

The term 'Classic Blues' refers to the songs of women singers based in New York and Chicago, particularly the larger-voiced contraltos who focused on blues and were backed by jazz musicians. Gertrude 'Ma' Rainey (1886–1939) was a significant example who was closest to the folk tradition. She was known as the 'Mother of the Blues', worked with Louis Armstrong on *Jelly Bean Blues* (1924), and made over 100 records in five years.

Bessie Smith (1894–1937) is probably the best known blues singer and her recording of *Down Hearted Blues* (1923) established her as the most successful black artist of the time. Her singing showed a powerful, emotional involvement, particularly noticeable in her slow blues songs.

The Influence of the Great Depression.

The poor conditions of the Depression may have partly triggered a more aggressive and powerful blues sound in the 1930s, with larger bands and the introduction of drummers and electrical amplification. This style of blues has been described as 'Urban Blues' and the guitarist Big Bill Broonzy (1893–1958) was an important exponent. In the early 1930s he added a trumpet, clarinet, a second guitar and a bass to make his Memphis Five Band, later adding a drummer. This created a music which had the drive needed for dancing. Other pioneers of Urban Blues include Tampa Red with his Chicago Five.

The evolution of blues into an ensemble-based genre continued after the war with singers like Muddy Waters (1915–83) and B.B. King (1925–2015). King, while remaining true to the blues form, explored aspects of jazz, gospel, and soul, with an innovative and expressive guitar technique.

The blues have continued to have a significant role in music, but the genre has been largely absorbed into popular music.

The Origins of Jazz.

It is difficult to give a comprehensive definition of jazz because of the variety of different styles within the genre. Generally, jazz shows a heightened preoccupation with rhythm, an emphasis on free improvisation, and usually a tonal/modal basis. Jazz emerged around the same time as the blues, and shares some of the latter's origins. Jazz has also had a significant influence on 'classical' composers, examples including Milhaud's *Le Creation du Monde* and Stravinsky's *Ragtime*.

Jazz originated in New Orleans around 1900, although the precise nature of the music played at that time is unclear because the earliest recording was made in 1917 by the white Original Dixieland Jazz Band. New Orleans jazz consisted of dense counterpoint from the front line wind instruments: saxophone, cornet, clarinet, and trombone, using material from the blues, marches or ragtime. The melody was usually embellished on the cornet with a higher counter-melody on the clarinet or saxophone. The rhythm section consisted of a piano, guitar or banjo playing the harmony, the drummer playing syncopated march rhythms, and a tuba or bass saxophone playing the bass line. There were short breaks for improvised solos from the wind players.

In the 1920s and 1930s the most innovative jazz musicians worked in Chicago and New York, and there was a musical shift towards more complex harmony, with a more subtle approach to improvisation. This can be seen in Bix Beiderbecke's (1903–31) cornet playing, for example *Davenport Blues* (1925) which shows a more expanded and imaginative approach to the improvised solo. Louis Armstrong (1901–71) with his Hot Five and Hot Seven had a more aggressive and rhythmically adventurous approach, which had a greater impact on the style.

Other significant bands that moved to Chicago in the 1920s include King Oliver's Creole Jazz Band and Jelly Roll Morton's band.

The 1920s.

In the 1920s another strand emerged known as orchestral jazz which can be seen in Fletcher Henderson's (1897 1952) band, partly due to the work of his arranger Don Redman. His approach to arranging was to use the sections: saxophones, brass (trumpets and trombones), and a rhythm section of banjo, tuba, piano and drums. Henderson created a combination of arranged big band sound with swinging jazz solos by such players as Louis Armstrong.

The term 'swing' describes the bands of the 1930s onwards, and also refers to the rhythmic approach where all quavers were 'swung' in a triplet rhythm. The difference between the 'swing' bands and their precursors is that the former had a greater control of the arrangement, and a tighter and more unified rhythm.

Duke Ellington.

Duke Ellington (1899–1974) and his Orchestra had a major impact on the development of big band composition, exploring a new range of expression. His compositions include miniature tone-poems such as *Daybreak Express* (1933), recompositions such as *Ebony Rhapsody* (1934) based on Liszt's *Hungarian Rhapsody No. 2* and solo concertos like *Clarinet Lament* (1936).

Benny Goodman (1909–86) was the significant white band leader of the period and succeeded in transforming Fletcher Henderson's approach with a more classically-based accuracy. He kept the swing element but removed the more adventurous approach to expression and note bending of the black bands.

Bebop.

In the 1940s a new style appeared called 'Bebop' or 'Bop' which consisted of complex, jagged, and stabbing harmonies, combined with free flowing scalic improvisation. The finest exponent of bebop was the alto saxophonist Charlie Parker (1920–55). He generally worked in small ensembles and played breathtaking improvisations of chromatic and irregular melodies, using rhythms which contradicted the underlaying pulse. Other important bebop players include the trumpeters Dizzy Gillespie and Miles Davis, and the pianist Thelonious Monk, all of whom played with Parker. Bebop marked a radical shift in the development of jazz as it allowed a much freer mode of expression, comparable with contemporary 'art' music.

Cool, Free Jazz and Fusion.

Miles Davis (1926-91) was unusual among jazz musicians as he successfully transformed his style several times, including swing, bebop, cool, modal jazz, fusion and funk. *The Birth of the Cool* (1949-50) with his own 9-piece band created a new sound which eschewed the frenetic activity of bebop for a drier, mellower, and 'cooler' sound. Other musicians working in this almost classical chamber of music style included Lennie Tristano and Gill Evans. In *A Kind of Blue* (1959) Davis continued his development into modal jazz where long stretches of music are based on one chord, with the improvised solos on a compatible mode.

The next step entailed removing the chord progressions completely, which Ornette Coleman (b. 1930) did in his 'free jazz' by removing harmony instruments from his groups. In addition, tempo and the time signature are variable in his work, giving his music a very fluid rhythmic flow. *Free Jazz* (1960) is Coleman's seminal recording, and his work was continued by the pianist Cecil Taylor and the trumpeter Don Cherry.

In the 1960s 'pop music' dominated the musical scene and in this period the use of electronics and musical elements from rock 'n' roll can be observed. Miles Davis' *Bitches Brew* (1969) is a good example of the fusion of jazz and rock. From 1970 to the present day the jazz scene has similar characteristics to that of contemporary 'art' music in the multiplicity of coexisting styles. This makes it difficult to identify a clear direction of development.

The most innovative current jazz performers include the pianist Keith Jarrett, George Russell, Anthony Braxton and Evan Parker.

Popular Music: Origins.

Popular Music can be defined as music which is aimed at the populace rather than an elite. Its abbreviated form 'pop', has been used since the 1950s, although one early use of this word was for a popular concert – first recorded in 1862. Popular music of the eighteenth and nineteenth centuries was briefer, simpler, and lighter than contemporaneous classical music.

In the early twentieth century, song writers such as Jerome Kern, Irving Berlin, George Gershwin, and Cole Porter, continued to develop the popular song often using 32 bar ballad form. This consisted of an introductory verse of 16 or 32 bars followed by a more memorable and lyrical chorus of 32 bars constructed of 4×8 bar sections: AABA. The songs were more imaginative than the above formula suggests and used sophisticated harmony influenced by both jazz and classical music. Tin Pan Alley was the area in New York City where many popular songs from the 1920s to 1950s were composed and published. 'Popular music' is now generally used for music since the 1950s with roots in rock 'n' roll, covering music as diverse as 'The Sex Pistols' and Cliff Richard.

Rock 'n' Roll and Rock.

Rock'n' roll is a form of rhythmicised blues, evolving from rhythm and blues, and was meant for dancing. Its tempo was fast and furious, the words were largely sexually based, the dynamic was loud, and the vocal style was both aggressive and semi-shouted. The instrumentation was dominated by electric guitars, saxophones, and a powerful rhythm section of drums, piano and bass, with a strong emphasis on the first beat of each bar. Major US performers include Bill Haley and his Comets, Jerry Lee Lewis, Elvis Presley, Chuck Berry and Little Richard.

The 1960s: The Beatles.

In the early 1960s rock 'n' roll was revitalised by the rise of new bands including the Beach Boys in the US and British groups such as the Beatles (*see* **B6**), the Rolling Stones, and the Who. These groups helped transform the genre into a varied and sophisticated form which became 'rock'. Also very important was the iconic music of David Bowie (*see* **B9**) and the works of Bob Dylan (*see* **B21**).

The main features of 'rock' were developed in California by the Byrds and other bands in San Francisco. Rock had the flexibility and potential to create more varied and complex structures. The Beatles illustrated this greater sophistication in albums such as *Revolver* (1966) and *Sgt. Pepper's Lonely Hearts Club Band* (1967). Their contribution to the development of popular music was immense through the unfolding of a varied and distinctive musical language, and also their evolution of studio techniques, including multi-tracking and sound processing. They disengaged their music from the 'live performance' which would have been impossible for many of their best recorded songs. Many rate the Beatles as the greatest rock 'n' roll artists of all time.

The basic characteristics of rock are an instrumentation of electric guitars, bass guitar, keyboard and drums; a fast, pounding rhythm from the bass and drums; and rather egocentric performances.

Michael Jackson: The 'King of Pop'.

Michael Jackson (1958–2009), the 'King of Pop' as he was widely acclaimed, was one of the most successful popular music entertainers of all time. His album *Thriller* (released in 1982) became an all-time bestseller. His performances were brilliant, but his personal life was troubled.

Born in Gary, Indiana, the seventh of nine children, he began performing at the age of 5. He subsequently became lead singer of the Jackson 5, but it was as a soloist that he found the greatest fame. His album *Thriller* (for which he will always be remembered) was followed by *Bad* (1987) and *Dangerous* (1991). A great dancer as well as a singer, his appeal was phenomenal – going beyond age, race or class. Michael Jackson also wrote and composed many of his greatest hits.

Heavy Metal.

Heavy metal was developed from the blues progressions of the late 1960s by 'power trios' like Cream and the Jimi Hendrix Experience. It consisted of guitar-based rock with highly amplified and virtuosic guitar and bass, creating a 'wall of sound'. In the 1970s heavy metal bands included Deep Purple, Steppenwolf and Black Sabbath who were followed by the new wave of British bands such as Def Leppard and Iron Maiden. Live performance is very important for heavy metal, as fans enjoy interacting with the performers.

Punk.

Punk was a term originally given to garage-based US rock of the 1960s, but was more famously used for music in 1976 played by the British bands, Sex Pistols, Clash, and Buzzcocks, who had been influenced by Richard Hell, and Patti Smith playing in New York City. Punk attempted to make rock 'dangerous' again, consisting of aggressive, anti-establishment lyrics, very basic guitar-based rock played at great speed. Punk evolved into New Wave which has similar energy but with more finesse and musical technique. Examples include Blondie and Talking Heads.

Reggae.

Reggae also emerged in the 1970s consisting of a

Jamaican pop style developed from Ska (a shuffling hybrid of rhythm and blues) and Mento. The music is much slower and more sensuous than other popular genres and has a hypnotic, bass-dominated sound, a 'chopped off' beat, and often a lyrical and expressive vocal line. Bob Marley was the most impressive performer, along with Desmond Dekker and Jimmy Cliff.

Disco, House and Techno.

In the last 40 years music for dancing has become prevalent through the Discotheque and latterly the 'Rave'. Disco consists of a thumping bass drum on each beat of the music and is considered a debased form of pop music. It was promoted by the film *Saturday Night Fever* (1977) and is a relatively simple style, making use of drum machines and synthesisers which give it an anonymous quality.

House is based on Disco and consists of the warm, feel-good music of the late 1980s. The term comes from the use of warehouses for performance, and it originated in Chicago with Frankie Knuckles. The 'godfather of house music' died in 2014. His biggest 'hit' was *The Whistle Song* in 1991.

Techno, originating in Detroit, was also a development of the 1980s. It is a percussion-based electronic dance music, with stripped-down drum beats and bass lines. UK labels include Rising High and Warp and successful groups are Prodigy, Orbital, and L.F.O.. Most techno uses a 'groove' or movement by repetition, which builds up an evolving musical texture like minimalist music.

Grunge.

Originating in Seattle during the mid-1980s, the grunge movement has largely usurped traditional heavy metal to become one of the most influential rock sounds of the 1990s. Essentially a mixture of blues-based chord progressions, punk-like energy levels and nihilistic lyrical content, the typical grunge song contrasts quieter, contemplative verses against raging, aggressive choruses. To achieve the deep and sinister sound at the heart of the music, grunge performers often de-tune their guitars and basses from standard concert pitch by up to two whole tones.

Since the movement came to world-wide prominence in 1992, grunge's most commercially successful acts have included Pearl Jam, Soundgarden and Alice In Chains. But by far the most important band to emerge from the genre was Seattle-based group Nirvana, whose second album, *Nevermind*, encapsulated much of grunge's intrinsic appeal. Unfortunately, Nirvana's singer/songwriter Kurt Cobain reacted badly to the demands of fame and subsequently took his own life in 1994. He has since become a cultural icon to disaffected teenagers everywhere. Though its forward momentum was temporarily checked by Cobain's death, grunge continues to grow with newer groups such as Live, Bush, Ash and Korn all expanding on the form's more dominant musical themes.

Brit-Pop.

After a particularly uneventful period in the history of British pop, a slew of similarlly themed bands emerged in 1993 and commercially re-invigorated the domestic music scene. Taking their blueprint from the sounds and styles of the 1960s—with the music of The Beatles and The Kinks a clear reference point—groups such as Manchester's Oasis, London's Blur and Sheffield's Pulp all but dominated the UK charts in the 1990s. In direct opposition to America's grunge movement, the lyrical content of much of Brit-Pop is optimistic in nature, with images of casual hedonism and wry social commentary well to the fore.

Conversely, as the genre continues to evolve, emergent acts such as Radiohead and The Verve are directly challenging the more formulaic aspects of the Brit-Pop sound. More 'rock' than 'pop', these groups employ odd time signatures, thicker orchestral textures and lyrical themes of paranoia and rigorous self-examination to inform their music. The result of such experimentation has meant that original Brit-Pop acts have been forced to re-evaluate their position and explore wider musical themes in an effort to compete.

Boy Bands/Girl Bands.

One of the more interesting developments to come out of the popular music scene was the increasing proliferation of boy/girl bands. Unlike most pop acts that hone their musical craft in rehearsal rooms and concert halls over a period of years, the majority of boy/girl bands are 'manufactured', with group members brought together by prospective managers through the process of audition.

As record producers and professional song-writers often provide these acts with their material, the skills required of the average boy/girl band member differ greatly from more traditional groups. In place of instrumental prowess, they must be youthful in appearance, able dancers and reasonably proficient singers. When marketed properly, these acts have achieved huge chart success, finding a dedicated fanbase consisting not only of teenagers, but also children very much younger.

A sterling example of a successful boy band was Take That, who enjoyed an almost Beatles-like public profile until their break-up at the start of 1996. (After his departure from Take That, Robbie Williams went on to achieve great acclaim as a soloist, reaching new pinnacles in his career).

Within months, Take That had been replaced in the public's affections by two more boy bands, Boyzone and the Backstreet Boys. They were followed later by One Direction.

By far the most commercially profitable of the all girl groups has been the Spice Girls, who dominated both the UK and US charts with their blend of soulful melodies and appealing dance routines. Their simple mantra of 'Girl Power' has also become a catchphrase for many teenagers.

Though boy and girl bands offer little in developmental terms to the course of popular music, their success indicated a trend towards a more generalised form of entertainment within the pop scene, where the ability to dance well was as highly prized as a fine singing voice.

Jungle.

Jungle is a loose term used to describe a frenetically paced form of dance music that originated in the UK 'rave/club' scene in the early 1990s. Like Techno music, jungle is percussion based and reliant on the use of drum machines and synthesisers to provide its centralised core. Yet, where it differs from techno and house music is in the profound absence of mid-range frequencies, with virtually no vocals or guitar used to enhance melody. Instead, both bass and treble frequencies are heavily compressed, creating a thunderous, filtered sound. To add to the sense of musical drama, jungle moves at a pace of approximately 156–180 BPM (beats per minute), almost double the speed of the average pop song.

Some of jungle music's more notable performers include Tricky and Goldie.

Drum and Bass.

Drum and bass is similar to jungle music in that it relies heavily on rhythm to enforce its point. However, in stark contrast to jungle's more repetitive approach, drum and bass often manipulates time signatures, speeding the beat up and down at irregular intervals to create a jarring musical effect. Because it compresses and stretches four bar progressions, drum and bass is often compared to jazz/bebop in terms of musical sensibility and performance. Roni Size is considered to be Great Britain's leading exponent of the drum and bass style.

Ambient.

Ambient is one of the most recent musical genres to emerge from the UK club scene. Effectively, it is a music of texture, where minimalist drum machine patterns and pulsating synthesisers are employed to invoke a sense of atmosphere and general relaxation. Less frenetic than either jungle or drum and bass, ambient is often played in smaller rooms within clubs.

II. GLOSSARY OF MUSICAL TERMS

A. Note of scale, commonly used for tuning instruments.

Absolute Music. Music without any literary descriptive or other kind of reference.

A Capella. Literally means "in the church style." Unaccompanied.

Accelerando. Quickening of the pace.

Accidental. The sign which alters the pitch of a note; ♯ (sharp) raises and a ♭ (flat) lowers note by one semitone, 𝄪 (double sharp) and 𝄫 (double flat) alter by two semitones.

Accompaniment. Instrumental or piano part forming background to a solo voice or instrument.

Ad lib. (L. *ad libitum*). Direction on music that strict time need not be observed.

Adagio. At a slow pace.

Aeolian mode. One of the scales in mediaeval music, represented by the white keys of the piano from A to A.

Air (Ayre). A simple tune for voice or instrument.

Alberti Bass. Characteristic 18th century keyboard figuration derived by splitting chord(s) of an accompanying part. Tradition credits Alberti as its inventor.

Allegretto. Not quite so fast as *Allegro*.

Allegro. Fast, but not too fast.

Alto. An unusually high type of male voice; also the vocal part sung by women and boys with a low range.

Ambrosian Chant. Plainsong introduced into church music by St. Ambrose, bishop of Milan (d. 397), and differing from Gregorian chant.

Andante. At a walking pace, not so slow as *Adagio* nor as fast as *Allegretto*.

Andantino. A little faster than *Andante*.

Animato. Lively.

Answer. Entry in a fugue or invention which imitates or "answers" the theme at a different pitch.

Anthem. Composition for use in church during a service by a choir with or without soloists.

Antiphonal. Using groups of instruments or singers placed apart.

Appoggiatura. An ornament consisting of a note just above or below a note of a chord, and resolving onto that note.

Arabesque. Usually a short piece, highly decorated.

Arco. Direction for string instruments to play with bow.

Aria. Vocal solo, usually in opera or oratorio, often in three sections with the third part being a repeat of the first. An *Arietta* is a shorter, lighter kind of aria.

Arioso. In the style of an aria; halfway between aria and recitative.

Arpeggio. Notes of a chord played in a broken, spread-out manner, as on a harp.

Ars antiqua. The old medieval music, based on organum and plainsong, before the introduction of *Ars nova* in 14th cent.

Ars Nova. New style of composition in 14th century France and Italy. It has greater variety in rhythm and independence in part-writing.

Atonal. Not in any key; hence *Atonality*.

Aubade. Morning song.

Augmentation. The enlargement of a melody by lengthening the time value of its notes.

Augmented. Enlarged verrsion of a perfect or major interval, *e.g.* semitone greater than a perfect fourth is an augmented fourth.

B. Note of scale, represented in Germany by *H*.

Bagatelle. A short, generally light piece of music. Beethoven wrote 26 Bagatelles.

Ballad. Either a narrative song or an 18th-cent. drawing-room song.

Ballade. A substantial and dramatic work, often for piano. Notable examples are by Chopin and Brahms.

Ballet. *See* **P38.**

Banjolele. A cross between a banjo and a ukelele.

Bar. A metrical division of music; the perpendicular line in musical notation to indicate this.

Barcarolle. A boating-song, in particular one associated with Venetian gondoliers.

Baritone. A male voice, between tenor and bass.

Baroque. A term applied, loosely, to music written in the 17th and 18th cent., roughly corresponding to baroque in architecture.

Bass. The lowest male voice; lowest part of a composition.

Bass Drum. Largest of the drum family, placed upright and struck on the side.

Bassoon. The lowest of the woodwind instruments, uses double reed.

Beat. Music's rhythmic pulse.

Bel canto. Literally "beautiful singing"—in the old Italian style with pure tone and exact phrasing.

Berceuse. Cradle song.

Binary. A piece in two sections is said to be binary in form. The balance is obtained by a second phrase (or section) answering the first.

Bitonality. Use of two keys at once.

Bow. Stick with horsehair stretched across it for playing string instruments.

Brass. Used as a collective noun for all brass or metal instruments.

Breve. Note, rarely used nowadays, with time value of two semibreves.

Bridge. Wood support over which strings are stretched on a violin, cello, *etc.*

Buffo(a). Comic, as in *buffo bass* or *opera buffa.*

C. Note of scale.

Cabaletta. Final, quick section of an aria or duet.

Cadence. A progression of two or three chords at the end of a phrase, section or piece.

Cadenza. Solo vocal or instrumental passage, either written or improvised, giving soloist chance to display technical skill to audience.

Calando. Becoming quieter and slower.

Canon. A piece or section of music resulting from one line of music being repeated in exact imitation in the other part(s) which enter in succession.

Cantabile. Song-like, flowing and expressive.

Cantata. Vocal work for soloist(s) and/or choir.

Cantilena. Sustained, smooth melodic line.

Cantus firmus. Literally "fixed song." Basic melody from 14th to 17th cent., around which other voices wove contrapuntal parts.

Canzonet. Light songs written in England *c.* 1600.

Carillon. A set of bells in tower of church, played from a keyboard below.

Carol. Christmas (or, less commonly, Easter) song.

Castrato. Artificially-created male soprano and alto, fashionable in 17th and 18th cent. (The castration of vocally gifted boys prevailed in Italy until the 19th cent.)

Catch. A part-song like a round, in vogue in England from 16th to 19th cent.

Cavatina. An operatic song in one section, or a slow song-like instrumental movement.

Celesta. Keyboard instrument with metal bars struck by hammers.

Cello (abbr. of *violoncello*). Four-stringed instrument, played with bow, with a bass range. Comes between viola and double bass in string family.

Cembalo. Originally the Italian name for the dulcimer, but also applied to the harpsichord.

Chaconne. Vocal or instrumental piece with repeated bass.

Chamber Music. Music for a relatively small number of performers (generally between two and ten).

Chanson. Type of part-song current in France from 14th to 16th cent.

Chant. Term used for various types of singing (generally in religious context), often of a rhythmically free nature.

Choir. Body of singers, used either in church or at concerts.

Chorales. German Lutheran hymns, often made use of by Bach.

Chord. Any combination of notes heard together. *See also* **Triad**.

Chording. Spacing of intervals in a chord.

Chorus. Substantial body of singers, usually singing in four parts.

Chromatic. Using a scale of nothing but semitones.

Clarinet. Woodwind instrument with single reed in use since mid-18th cent.

Clavichord. Keyboard instrument having strings struck by metal tangents, much in use during 17th and 18th cent. as solo instrument.

Clavier. Keyboard. Used in German (*Klavier*) for piano.

Clef. Sign in stave that fixes place of each note.

Coda. Closing section of a composition.

Coloratura. Term to denote florid singing.

Common chord. *See* Triad.

Common Time. Four crotchets to the bar, 4/4 time.

Compass. Range of notes covered by voice or instruments.

Composition. Piece of music, originated by a composer's own imagination; act of writing such a piece.

Compound Time. Metre where beats are subdivided into threes rather than twos. *See* Simple time.

Con Brio. With dash.

Concert. Public performance of any music.

Concertato. Writing for several solo instruments to be played together.

Concerto. Work for one or more solo instruments and orchestra.

Concerto grosso. Orchestral work common in 17th and 18th cent. with prominent parts for small groups of instruments.

Concord. Opposite of discord, *i.e.*, notes that when sounded together satisfy the ear. (Conventional term in that its application varies according to the predominant musical style of the period.)

Consecutive. Progression of harmonic intervals of like kind.

Consonance. Like Concord.

Continuo. Bass line in 17th and 18th century music. Played by a bass instrument and keyboard, the latter improvising on the indicated harmonies.

Contralto. A woman's voice with a low range.

Counterpoint. Simultaneous combination of two or more melodies to create a satisfying musical texture. Where one melody is added to another, one is called the other's counterpoint. The adjective of counterpoint is contrapuntal.

Counter-tenor. Another name for male alto.

Courante. A dance in triple time.

Crescendo. Getting louder.

Crook. Detachable section of tubing on brass instruments that change the tuning.

Crotchet. Note that equals two quavers in time value.

Cycle. Set of works, especially songs, intended to be sung as group.

Cyclic form. Form of work in two or more movements in which the same musical themes recur.

Cymbal. Percussion instrument in the form of a metal plate; often two are struck against each other.

D. Note of scale.

Da Capo (abbr. D.C.). From the beginning. A *Da Capo* aria is one in which the whole first section is repeated after a contrasting middle section.

Descant. Additional part (sometimes improvised) sung against a melody.

Development. Working-out section of movement in sonata form. *See* Sonata.

Diatonic. Opposite of chromatic; using proper notes of a major or minor scale.

Diminished. Lessened version of perfect or minor interval, *e.g.*, semitone less than a perfect fifth is a diminished fifth.

Diminuendo. Becoming quieter.

Diminution. Reducing a phrase of melody by shortening time value of notes.

Discord. Opposite of concord, *i.e.*, notes that sounded together produce a clash of harmonies.

Dissonance. Like discord.

Divertimento. A piece, usually orchestral, in several movements; like a suite.

Dodecaphonic. Pertaining to 12-note method of composition.

Dominant. Fifth note of major or minor scale above tonic (key) note.

Dorian Mode. One of the scales in medieval music, represented by the white keys on the piano from D to D.

Dot. Placed over note indicates staccato; placed after note indicates time value to be increased by half.

Double bar. Two upright lines marking the end of a composition or a section of it.

Double bass. Largest and lowest instrument of violin family; played with bow or plucked.

Drone. Unvarying sustained note, often in the bass, for example, the permanent bass note of a bagpipe.

Drum. Variety of percussion instruments on which sound is produced by hitting a skin stretched tightly over a hollow cylinder or hemisphere.

Duet. Combination of two performers; composition for such a combination.

Duple Time. Metre in which there are two beats to a bar.

Dynamics. Gradations of loudness or softness in music.

E. Note of scale.

Encore. Request from audience for repeat of work, or extra item in a programme.

English horn (*Cor anglais*). Woodwind instrument with double reed of oboe family with lower range than oboe.

Enharmonic. Refers to use of different letter names for the same note, *e.g.* F and E♯. Often exploited to achieve modulation between distantly related keys.

Ensemble. Teamwork in performance; item in opera for several singers with or without chorus; a group of performers of no fixed number.

Episode. Section in composition occurring between appearances of main musical material.

Exposition. Setting out of thematic material in a sonata-form composition.

Expression marks. Indication by composer of how he wants his music performed.

F. Note of scale.

False relation. A clash of harmony produced when two notes of the same letter-name but differently inflected (*e.g.* A natural and A flat) are played simultaneously or straight after one another.

Falsetto. The kind of singing by male voices above normal register and sounding like an unbroken voice.

Fanfare. Flourish of trumpets.

Fantasy. A piece suggesting free play of composer's imagination, or a piece based on known tunes (folk, operatic, *etc.*).

Fermata. Pause indicated by sign 𝄐 prolonging note beyond its normal length.

Fifth. Interval taking five steps in the scale. A perfect fifth (say, C to G) includes three whole tones and a semitone; a diminished fifth is a semitone less, an augmented fifth a semitone more.

Figure. A short phrase, especially one that is repeated.

Fingering. Use of fingers to play instrument, or the indication above notes to show what fingers should be used.

Flat. Term indicating a lowering of pitch by a semitone, or to describe a performer playing under the note.

Florid. Term used to describe decorative passages.

Flute. Woodwind instrument, blown sideways. It is played through a hole, not a reed. Nowadays, sometimes made of metal.

Folksong. Traditional tune, often in different versions, handed down aurally from generation to generation.

Form. Course or layout of a composition, especially when in various sections.

Fortissimo. Very loud.

Fourth. Interval taking four steps in scale. A perfect fourth (say, C to F) contains two whole tones and a semitone. A diminished fourth is a semitone less, and an augmented fourth a semitone more.

Fugato. In the manner of a fugue.

Fugue. Contrapuntal composition for various parts based on one or more subjects treated imitatively.

G. Note of scale.

Galant. Used to designate elegant style of 18th-cent. music.

Galliard. Lively dance dating back to 15th cent. or before.

Gamelan. A percussion orchestra from Indonesia.

Gavotte. Dance in 4/4 time, beginning on third beat in bar.

Giusto. Strict, proper.

Glee. An unaccompanied part-song. *See* **Section L.**

Glissando. Rapid sliding scales up and down piano or other instruments.

Glockenspiel. Percussion instrument consisting of tuned steel bars and played with two hammers or keyboard.

Grave. In slow tempo.

Grazioso. Gracefully.

Gregorian Chant. Plainsong collected and supervised mainly by Pope Gregory (d. 604).

Ground Bass. A bass part that is repeated throughout a piece with varying material on top.

Guitar. Plucked string instrument of Spanish origin, with six strings of three-octave compass.

H. German note-symbol for *B*.

Harmony. Simultaneous sounding of notes so as to make musical sense.

Harp. Plucked string instrument of ancient origin, the strings stretched parallel across its frame. On the modern concert harp, the basic scale of C flat major is altered by a set of pedals.

Harpsichord. Keyboard stringed instrument played by means of keyboard similar to a piano but producing its notes by a plucking, rather than a striking action.

Homophonic. Opposite of polyphonic, *i.e.*, indicated parts move together in a composition, a single melody being accompanied by block chords, as distinct from the contrapuntal movement of different melodies.

Horn. Brass instrument with coiled tubes. Valves introduced in the 19th cent. made full chromatic use of instrument possible.

Imitation. Repetition, exactly, or at least recognisably, of a previously heard figure.

Impromptu. A short, seemingly improvised piece of music, especially by Schubert or Chopin.

Improvise. To perform according to fancy or imagination, sometimes on a given theme.

In alt. The octave above the treble clef; *in altissimo*, octave above that.

Instrumentation. Writing music for particular instruments, using the composer's knowledge of what sounds well on different instruments.

Interlude. Piece played between two sections of a composition.

Intermezzo. Formerly meant interlude, now often used for pieces played between acts of operas.

Interval. Distance in pitch between two notes.

Ionian mode. One of the scales in mediaeval music, represented on piano by white keys between C and C, identical therefore to modern C major scale.

Isorhythm. Medieval technique using repetitions of a rhythm but with different notes. Much used in 14th and 15th century motets. *See* **P3–4**.

Jig. Old dance usually in 6/8 or 12/8 time.

Kettledrum (It. pl. *Timpani*). Drum with skin drawn over a cauldron-shaped receptacle, can be tuned to definite pitch by turning handles on rim, thus tightening or relaxing skin.

Key. Lever by means of which piano, organ, *etc.*, produces note; classification, in relatively modern times, of notes of a scale. Any piece of music in major or minor is in the *key* of its tonic or keynote.

Keyboard. Term used to describe instruments with a continuous row of keys.

Key-signature. Indication on written music, usually at the beginning of each line, of the number of flats or sharps in the key of a composition.

Kitchen Department. Humorous term for percussion section of an orchestra.

Lament. Musical piece of sad or deathly significance.

Largamente. Spaciously.

Largo. Slow.

Leading-motive (Ger. *Leitmotiv*). Short theme, suggesting person, idea, or image, quoted throughout composition to indicate that person, *etc.*

Legato. In a smooth style (of performance, *etc.*).

Lento. Slow.

Libretto. Text of an opera. *See* **Section L.**

Lied (pl. *Lieder*). German word for song, particularly used of the songs with piano accompaniment of Schubert, Schumann, Brahms, and Wolf.

Lute. String instrument plucked with fingers, used in 16th- and 17th-cent. music especially.

Lydian mode. One of the scales in mediaeval music, represented by white keys of piano between F and F.

Lyre. Ancient Greek plucked string instrument.

Madrigal. Composition for several voices, setting secular text; especially prominent in Italy and England in 16th and early 17th cent. *See* **P5**.

Maestoso. Stately.

Major. One of the two main scales of the tonal system with semitones between the third and fourth, and the seventh and eighth notes. Identical with Ionian mode.

Mandolin(e). Plucked string instrument of Italian origin.

Manual. A keyboard for the hands, used mostly in connection with the organ.

Master of the King's (or Queen's) Musick. Title of British court appointment, with no precise duties.

Melisma. Group of notes sung to a single syllable.

Mélodie. Literally a melody or tune; has come to mean a French song (*cf.* German *Lied*).

Metronome. Small machine in use since the beginning of the 19th cent., to determine the pace of any composition by the beats of the music, *e.g.*, ♩ = 60 at the head of the music indicates sixty crotchets to the minute.

Mezzo, Mezza. (It. = "half ") *Mezza voce* means using the half voice (a tone between normal singing and whispering). *Mezzo-soprano*, voice between soprano and contralto.

Minim. Note that equals two crotchets in time value.

Minor. One of the two main scales of the tonal system (cf. major), identical with Aeolian mode. It has two forms—the harmonic and melodic, the former having a sharpened seventh note, the latter having the sixth and seventh notes sharpened in its ascending version.

Minuet. Originally French 18th-cent. dance in triple time, then the usual third movement in symphonic form (with a contrasting trio section) until succeeded by scherzo.

Mixolydian mode. One of the medieval scales represented by the white keys on the piano from G to G.

Modes. Scales prevalent in the Middle Ages. *See* Aeolian, Dorian, Ionian, Lydian, Mixolydian, Phrygian.

Modulate. Changing from key to key in a composition, not directly but according to musical "grammar".

Molto. Much, very; thus *allegro molto*.

Motet. Sacred, polyphonic vocal composition. More loosely, any choral composition for use in church but not set to words of the liturgy. *See* **P3**.

Motive, motif. Short, easily recognised melodic figure.

Motto. Well-defined theme recurring throughout a composition, *cf. Idée fixe* in Berlioz's *Symphonie Fantastique*.

Movement. A piece which is complete in itself but forms part of a larger composition.

Music drama. Term used to describe Wagner's, and sometimes other large-scale operas.

Mutes. Devices used to damp the sound of various instruments.

Natural (of a note or key). Not sharp or flat.

Neoclassical. Clear-cut style, originating during 1920s, that uses 17th and 18th century forms and styles. It constituted a reaction to the excesses of romanticism.

Ninth. Interval taking nine steps, *e.g.*, from C upwards an octave and a whole tone to D.

Nocturne. Literally a "night-piece" hence usually of lyrical character.

Nonet. Composition for nine instruments.

Notation. System of writing down music.

Note. Single sound of specified pitch and duration; symbol to represent this.

Obbligato. Instrumental part having a special or essential rôle in a piece.

Oboe. Woodwind instrument with double reed, descended from hautboy; as such, in use since 16th cent., in modern form since 18th cent.

Octave. Interval taking eight steps of scale, with top and bottom notes having same "name"; C to C is an octave.

Octet. Composition for eight instruments or voices.

Ondes Martenol. Belongs to a class of melodic instruments in which the tone is produced by electrical vibrations controlled by the movement of the hands not touching the instrument.

Opera. Musical work for the stage with singing characters, originated *c.* 1600 in Italy.

Opera buffa (It.), **Opéra bouffe** (Fr.). Comic opera (in the English sense), *not* to be confused with *Opéra comique* (Fr.) which is opera with spoken dialogue and need not be humorous.

Opera seria. Chief operatic form of 17th and 18th cent., usually set to very formal librettos, concerning gods or heroes of ancient history.

Operetta. Lighter type of opera.

Opus (abbr. *Op.*). With number following *opus* indicates order of a composer's composition.

Oratorio. Vocal work, usually for soloists and choir with instrumental accompaniment, generally with setting of a religious text.

Orchestra. Term to designate large, or largish, body of instrumentalists; originated in 17th cent.

Orchestration. Art of setting out work for instruments of an orchestra. To be distinguished from *Instrumentation* (*q.v.*).

Organ. Elaborate keyboard instrument in which air is blown through pipes by bellows to sound notes. Tone is altered by selection of various stops and, since the 16th cent., a pedal keyboard has also been incorporated.

Organum. In medieval music a part sung as an accompaniment below or above the melody of plainsong, usually at the interval of a fourth or fifth; also, loosely, this method of singing in parts.

Ornament. Notes that are added to a given melody by composer or performer as an embellishment.

Overture. Instrumental introduction or prelude to larger work, usually opera. A concert overture is an independent orchestral piece, not part of an opera but often having a descriptive character.

Part. Music of one performer in an ensemble; single strand in a composition.

Part-song. Vocal composition in several parts.

Passacaglia. Composition in which a tune is constantly repeated, usually in the bass.

Passage. Section of a composition.

Passion. Musical setting of the New Testament story of Christ's trial and crucifixion.

Pastiche. Piece deliberately written in another composer's style.

Pavan(e). Moderately paced dance dating from 16th cent. or earlier.

Pedal point. Held note, usually in bass, against which other parts move.

Pentatonic. Scale of five notes, *e.g.*, the black keys of the piano.

Percussion. Collective title for instruments of the orchestra that are sounded by being struck by hand or stick.

Phrygian Mode. One of the scales of medieval music, represented by the white keys on piano from E to E.

Piano. Soft, abbr. *p*; *pp=pianissimo*, very soft; instrument, invented in 18th cent., having strings struck by hammer, as opposed to the earlier harpsichord where they are plucked. The modern piano has 88 keys and can be either "upright" (vertical) or "grand" (horizontal).

Pianoforte. Almost obsolete full Italian name for the piano.

Pitch. Exact height or depth of a particular musical sound or note.

Pizzicato. Direction for stringed instruments, that the strings should be plucked instead of bowed.

Plainchant, Plainsong. Medieval church music consisting of single line of melody without harmony or definite rhythm. *See* **P3**.

Polka. Dance in 2/4 time originating in 19th cent. Bohemia.

Polonaise. Polish dance generally in 3/4 time.

Polyphony. Combination of two or more musical lines as in *counterpoint.*

Polytonality. Simultaneous use of several keys.

Postlude. Closing piece or section.

Prelude. Introductory piece.

Presto. Very fast. *Prestissimo.* Still faster.

Progression. Movement from one chord to next to make musical sense.

Quartet. Work written for four instruments or voices; group to play or sing such a work.

Quaver. Note that equals two semiquavers or half a crotchet.

Quintet. Work written for five instruments or voices; group to play or sing such a work.

Rallentando. Slowing down.

Recapitulation. Section of composition that repeats original material in something like its original form.

Recitative. Term used for declamation in singing written in ordinary notation but allowing rhythmical licence.

Recorder. Woodwind instrument, forerunner of flute.

Reed. Vibrating tongue of woodwind instruments.

Register. Set of organ pipes controlled by a particular stop; used in reference to different ranges of instrument or voice (*e.g.*, chest register).

Relative. Term used of major and minor keys with a common key-signature (*e.g.* G major and E minor).

Répétiteur. Member of opera house's musical staff who coaches singers in their parts.

Requiem. Properly a mass for the dead, the term is extended to cover musical settings by Palestrina, Mozart, Verdi and others.

Rest. Notation of silence in composition, having a definite length like a note.

Retrograde. Term used to describe a melody played backwards.

Rhapsody. Work having a free form with a degree of romantic content.

Rhythm. Everything concerned with the time of music (*i.e.*, beats, accent, metre, *etc.*) as opposed to the pitch side.

Ritardando. Slowing down.

Ritenuto. Held back (referring to tempo).

Ritornello. Passage, usually instrumental, that recurs in a piece.

Romance, Romanza. Title for piece of vague song-like character.

Romantic. Term used vaguely to describe music of 19th cent. that often has other than purely musical source of inspiration.

Rondo. Form in which one section keeps on recurring between other passages.

Rubato. Manner of performing a piece without keeping strictly to time.

Sackbut. Early form of trombone.

Saxophone. Wind instrument made of brass, but using a reed like a woodwind instrument.

Scale. Progression of adjoining notes upwards or downwards.

Scherzo. Literally "a joke". Often used as a light movement in the middle of a sonata type work.

Score. Copy of any music written in several parts.

Second. Interval taking two steps in scale, *e.g.*, C to D flat, or to D.

Semibreve. Note that equals two minims or half a breve.

Semiquaver. Note that equals half a quaver.

Semitone. Smallest interval commonly used in Western music.

Septet. Composition for seven instruments or voices.

Sequence. Repetition of phrase at a higher or lower pitch.

Serenade. Usually an evening song or instrumental work.

Seventh. Interval taking seven steps in the scale.

Sextet. Composition for six instruments or voices.

Sharp. Term indicating a raising of pitch by a semitone.

Shawm. Early woodwind instrument, forerunner of oboe.

Simple time. Metre in which beats are subdivided into two. *See* Compound time.

Sinfonietta. Small symphony.

Sixth. Interval taking six steps in the scale.

Solo. Piece or part of a piece for one performer playing or singing alone.

Sonata. Work for one or two players (occasionally more), generally in three or four movements. **Sonata form** is the form usually found in the first movement (and often in subsequent movements) many sonatas and symphonies, consisting of exposition, development and recapitulation.

Song. Any short vocal composition.

Soprano. Highest female voice.

Sostenuto. Sustained, broadly.

Sotto voce. Whispered, scarcely audible, applied to vocal as well as instrumental music.

Spinet. A small keyboard instrument belonging to the harpsichord (*q.v.*) family.

Spirituals, Afro-American melodies with religious inspiration and which are still spontaneously created, but have also passed into art-music.

Sprechgesang. (Ger. Speech-song.) Vocal utterance somewhere between speech and song.

Staccato. Perform music in short, detached manner.

Staff. Horizontal lines on which music is usually written.

Stop. Lever by which organ registration can be altered.

String(s). Strands of gut or metal set in vibration to produce musical sounds on string or keyboard instruments. Plural refers to violins, violas, cellos, and basses of orchestra.

Study. Instrumental piece, usually one used for technical exercise or to display technical skills, but often having artistic merits as well (*e.g.*, Chopin's).

Subject(s). Theme or group of notes that forms principal idea or ideas in composition.

Suite. Work in several movements. The dance suite was a favourite instrumental form in the early 18th century.

Symphony. Orchestral work of serious purpose usually in four movements, occasionally given name (*e.g.*, Beethoven's "Choral" symphony).

Syncopation. Displacement of musical accent.

Tempo. Pace, speed of music.

Tenor. Highest normal male voice.

Ternary. A piece in three sections is said to be in ternary form. The balance is obtained by repeating the first phrase or section (though it need not be exact or complete) after a second of equal importance.

Tessitura. Compass into which voice or instrument comfortably falls.

Theme. Same as *subject* but can also be used for a whole musical statement as in "theme and variations."

Third. Interval taking three steps in scale.

Time. Rhythmical division of music.

Timpani. *See* **Kettledrum.**

Toccata. Instrumental piece usually needing rapid, brilliant execution.

Tonality. Key, or feeling for a definite key.

Tone. Quality of musical sound; interval of two semitones.

Tonic Sol-fa. System of musical notation to simplify sight-reading.

Transcribe. Arrange piece for different medium from that originally intended; transfer piece from one style of notation to another; notate an originally unnotated piece.

Transition. Passage that joins two themes or sections of a composition.

Transpose. To move a musical idea, theme or piece to a different key from its original.

Treble. Highest part in vocal composition; high boy's voice.

Triad. Three note chord. Usually consists of a note and those a third and fifth above.

Trio. Work written for three instruments or voices; group to play or sing such a work.

Trombone. Brass instrument with slide adjusting length of tube.

Trumpet. Brass instrument of considerable antiquity; modern version has three valves to make it into a chromatic instrument.

Tuba. Deepest-toned brass instrument with three or four valves.

Twelve-note. 20th-cent. technique of composition using full chromatic scale with each note having equal importance. Notes are placed in particular order as the basis of works.

Unison. Two parts sung or played together at same pitch.

Valve. Mechanism, invented in early 19th cent. to add to brass instruments allowing them to play full chromatic scale.

Variation. Altered version of theme or passage. Such variations may be closely allied to or depart widely from the original.

Verismo. Term to describe Italian operas written in "realist" style at the turn of the 20th century.

Vibrato. Rapid fluctuation in pitch of voice or instrument. Exaggerated it is referred to as a "wobble" (of singers).

Viol. String instrument of various sizes in vogue until end of 17th cent.

Viola. Tenor instrument of violin family.

Violin. Musical four-string instrument, played with bow, which superseded viol at beginning of 18th cent.

Virginals. English keyboard instrument, similar to harpsichord of 17th and 18th cent.

Vivace. Lively.

Voluntary. Organ piece for church use, but not during service.

Waltz. Dance in triple time, fashionable in 19th cent. *See* **P36**.

Whole-tone scale. Scale progressing by whole tones. Only two are possible, one beginning on C, the other on C sharp.

Xylophone. Percussion instrument with series of wood bars tuned in a chromatic scale and played with sticks.

Zarzuela. A traditional Spanish form of operetta.

Zither. String instrument laid on knees and plucked. Common in Central-European folk music.

III. INDEX TO COMPOSERS

Adams, John (b. 1947) 21(2)
Adès, Thomas (b. 1971) 23(2)
Albéniz, Isaac (1860–1909) 15(1)
Albinoni, Tommaso (1671–1750) 6(1)
Babbitt, Milton (1916–2011) 19(2)
Bach, Carl Philipp Emanuel (1714–88) 7(1)
Bach, Johann Christian (1735–82) 7(1)
Bach, Johann Sebastian (1685–1750) 6
Balakirev, Mily (1837–1910) 11(2)
Bartók, Bela (1881–1945) 13(1)
Beethoven, Ludwig van (1770–1827) 8
Bellini, Vincenzo (1801–35) 10(1)
Benjamin, George (b. 1960) 22(2)
Berg, Alban (1885–1935) 16(2)
Berio, Luciano (1925–2003) 22(1)
Berlioz, Hector (1803–69) 9(1)
Biber, Heinrich (1644–1704) 5(2)
Birtwistle, Sir Harrison (b. 1934) 22(1),24(1)
Bizet, Georges (1838–75) 14(1)
Blow, John (1649–1708) 5(2)
Boccherini, Luigi (1743–1805) 9(1)
Boito, Arrigo (1842–1918) 10(2)
Borodin, Alexander (1833–87) 11(2)
Boulez, Pierre (1925–2016) 19(2),24(1)
Brahms, Johannes (1833–97) 10(2)
Britten, Benjamin (1913–76) 18(2)
Brown, Earle (b. 1926) 20(2)
Bruckner, Anton (1824–96) 11(1)
Busoni, Ferruccio (1866–1924) 17(1)
Butler, Martin (b. 1960) 23(1)
Buxtehude, Dietrich (1637–1707) 5(2)
Byrd, William (*c.* 1540–1623) 4(2)
Cabezón, Antonio de (*c.* 1510–66) 5(1)
Caccini, Giulio (*c.* 1545–1618) 5(1)
Cage, John (1912–92) 20(2), 21(2)
Carissimi, Giacomo (*c.* 1604–74) 5(1)
Carter, Elliott (1908–2012) 19(1)
Cavalieri, Emilio del (*c.* 1550–1602) 5(2)
Cavalli, Pietro Francesco (1602–76) 5(1)
Cesti, Marc'Antonio (1623–69) 5(1)
Chopin, Frederic François (1810–49) 9(2)
Cimarosa, Domenico (1749–1801) 9(1)
Copland, Aaron (1900–90) 18(1)
Corelli, Arcangelo (1653–1713) 6(1)
Cui, César (1835–1918) 11(2)
Dallapiccola, Luigi (1904–75) 19(2)
Davies, Sir Peter Maxwell (1934–2016) 20(1),22(1)
Debussy, Claude (1862–1918) 14(1)
de la Halle, Adam (fl. *c.* 1250–1300) 3(2)
Delius, Frederick (1862–1934) 18(2)
d'Indy, Vincent (1851–1931) 14(2)
Donizetti, Gaetano (1797–1848) 10(1)
Dufay, Guillaume (1400–74) 4(1)
Dukas, Paul (1865–1935) 14(2)
Dunstable, John (1385–1453) 4(1)
Duparc, Henri (1844–1933) 14(2)
Dussek, Jan Ladislav (1760–1812) 9(1)
Dvořák, Antonin (1841–1904) 12(1)
Elgar, Sir Edward (1857–1934) 13(2)
Falla, Manuel de (1876–1946) 15(1)
Farnaby, Giles (*c.* 1563–1640) 5(1)
Fauré, Gabriel (1845–1924) 14(1)
Ferneyhough, Brian (b. 1943) 23(1)
Franck, César (1822–90) 14(1)
Franco of Cologne (mid 13th cent.) 4(1)
Frescobaldi, Girolamo (1583–1643) 5(1)
Gabrieli, Andrea (*c.* 1510–86) 4(2)
Gabrieli, Giovanni (1553/56–1612) 4(2)
Geminiani, Francesco (1687–1762) 6(1)
Gesualdo, Carlo (1561–1613) 5(1)
Gibbons, Orlando (1583–1625) 5(1)
Giordano, Umberto (1867–1948) 17(2)
Glass, Philip (b. 1937) 21(2)
Glinka, Mikhail (1804–57) 11(2)
Gluck, Christoph Wilibald (1714–87) 7(2)
Gombert, Nicolas (*c.* 1500–56) 4(2)
Gounod, Charles (1818–93) 14(1)
Granados, Enrique (1867–1916) 15(1)
Grieg, Edvard (1843–1907) 13(2)
Guido d'Arrezo, (*c.* 991/2–*c.* 1033) 3(2)
Halévy, Jacques François (1799–1862) 10(1)
Handel, George Frederic (1685–1759) 6
Hauer, Josef (1883–1959) 16(2)
Haydn, Franz Joseph (1732–1809) 7
Henze, Hans Werner (1926–2012) 21(2)
Hindemith, Paul (1895–1963) 18(1)
Holst, Gustav (1874–1934) 18(1)
Honegger, Arthur (1892–1955) 15(1)
Humfrey, Pelham (1647–74) 6(1)
Hummel, Johann Nepomuk (1778–1837) 9(1)
Isaac, Heinrich (*c.* 1450–1517) 4(2)
Ives, Charles (1874–1954) 18(1)
Janáček, Leoš (1858–1928) 12(2)
Josquin des Prés (1440–1521) 4(1)
Knussen, Oliver (b. 1952) 22(2)
Kodály, Zoltán (1882–1967) 13(1)
Lassus, Orlandus (*c.* 1532–94) 4(2)
Lawes, Henry (1596–1662) 5(2)
Leoncavallo, Ruggiero (1858–1919) 17(2)
Leonin (12th cent.) 3(2)
Ligeti, György (1923–2006) 20(1)
Liszt, Franz (1811–86) 9(1)
Lully, Jean-Baptiste (*c.* 1632–87) 5(2)
Lutoslawski, Witold (1913–93) 20(2)
Machaut, Guillaume de (1300–77) 4(1)
MacMillan, James (b. 1959) 23(1)
Mahler, Gustav (1860–1911) 15(2)
Marenzio, Luca (*c.* 1553–99) 5(1)
Martland, Steve (1959–2013) 23(1)
Mascagni, Pietro (1863–1945) 17(2)
Massenet, Jules Emile Frédéric (1842–1912) 14(1)
Méhul, Etienne Nicolas (1763–1817) 9(1)
Mendelssohn, Felix (1809–47) 9(1)

IV. SPECIAL TOPIC

DANCE IN THE WEST.

SOCIAL DANCES.

In earliest times, dances performed solely for the enjoyment of the participants were what we would now term folk dances. In these, the dancers formed a pattern such as a circle or a line, and all performed the same steps. Such dances still exist but are now more likely to be performed as an entertainment rather than as a purely social activity. A different type of social dancing developed in Europe from medieval times, with couples dancing together. The *pavane*, a majestic, processional dance in a four-in-a-measure (occasionally two) rhythm, and the contrasting *galliard*, with rapid and complex steps to three-in-a-measure, both originating from Italy, were popular in the sixteenth century. In the seventeenth century, the *minuet* and the *gavotte* were popular dances at the court of Louis XIV of France. Both were slow, stately dances but in different rhythms, the minuet in a measure of three and the gavotte in four. These dances were imported into England by Charles II and kept their popularity for many years, the minuet especially, which was the most favoured dance of the eighteenth century until about 1790.

The style of social dance in the Europe and America of the nineteenth and twentieth centuries was, however, overwhelmingly ballroom dance, performed by couples and including such dances as the waltz, fox-trot and polka as well as Latin-American inspired dances such as the tango, rumba and samba, and this was dominant until the more individualistic discotheque styles of the 1960s onwards.

The following are in very approximate order of appearance.

Tarantella.

A folk dance of Italy in accelerating 3/8 or 6/8 time, usually danced by couples. Its name is derived from the city of Taranto where in the fourteenth century, according to legend, people bitten by the tarantula spider danced to sweat the poison out of their systems.

Mazurka.

A Polish national dance for a circle of couples, first recorded in the sixteenth century. Danced in triple time with the accent on the second or third beat, it is characterised by foot stamping and clicking of heels. It became popular as a ballroom dance in Europe and the United States in the late nineteenth century.

Square Dance.

The best-known and most popular folk dance in the United States. Danced by four couples standing in a square, whose movements, based on a smooth 'shuffling' walk, are prompted by the singing and patter of a 'caller'. Its origins can be traced to earlier dances in square formation such as the *cotillon*, a stately French dance popular at the court of Louis XV later supplanted by the *quadrille*, and to the intermingling of the various dances brought to the New World from Europe by the first settlers. After being eclipsed in the cities by new modern dances in the nineteenth and early twentieth centuries, it enjoyed a revival in the 1930s and 40s which has maintained its popularity.

Line Dancing.

Essentially any dance where groups of dancers standing in a line (or lines) perform the same moves, but usually referring to country and western style line dances whose origins probably go back to the first American settlers. This style of dancing enjoyed a renaissance in America during the 1970s. It arrived in the UK in the 1990s, where it is still popular.

Waltz.

The first of the modern ballroom dances, the waltz originated in central Europe in the eighteenth century and was derived from the *Ländler*, a traditional couple dance of Bavaria and Austria. Danced to music in 3/4 time, it consists of a step-slide-step pattern performed by couples rotating around each other as they circle the dance floor – rapidly in the original Viennese waltz, more slowly in its later American version. It was initially seen as degenerate but became the most popular ballroom dance of the nineteenth century.

Polka.

A vigorous Bohemian dance to music in 2/4 time, the polka consists of three quick steps and a hop (the Czech *pulka*, 'half step'). Introduced in Paris in 1843, it became a serious rival in popularity to the waltz.

Quadrille.

An early nineteenth-century ballroom dance for couples in a square formation. Popular in France at the court of Napoleon I, it was brought to England in 1815.

Lancers.

A nineteenth-century variant of the *quadrille*. From *Quadrille des lanciers*, a dance invented in Dublin in 1818 by a French dancing teacher.

Barn Dance.

A rural American dance introduced into Britain in the late nineteenth century. Derived from the *Schottische*, a German couple dance, it was originally called the Military Schottische. The origin of its current name is uncertain as it may refer to dancing in a barn or it may refer to its being first danced to a song with the title *Dancing in the Barn*.

Cakewalk.

A dance of Afro-American origin in the nineteenth century, modelled on walking competitions in the southern states. It is named from the cake given as a prize for the most imaginative steps. Performed by a couple strutting arm-in-arm, it became a ballroom dance towards the end of the century after gaining popularity through stage shows.

Tango.

Originated as a rather disreputable dance in Buenos Aires, Argentina, about 1880. After becoming socially acceptable in the early 1900s it became highly popular in Europe by 1915. It is characterised by rapid long steps and sudden turns of the head and feet.

Fox-trot.

Introduced around 1914, it was named from the trotting step in the comedian Harry Fox's act. It consists of a series of walking steps and quarter turns, two slow steps forward then two quick steps to the side, to music in syncopated 4/4 rhythm.

Charleston.

Popular dance craze of the mid-1920s, originally an Afro-American solo dance and named after Charleston, South Carolina, where it was first performed in 1903. It is a fast-tempo dance to a syncopated 4/4 rhythm and the basic step is side-kicking from the knee.

Black Bottom.

Popular dance of the 1920s of Afro-American origin in New York, incorporating shuffling, stomping steps and swaying knees to a rhythm based on the Charleston.

Quickstep.

A dance in duple time, originating in the 1920s, which is basically a faster version of the fox-trot.

Rumba.

A Cuban dance of two quick side steps and one slow forward step to syncopated 4/4 time music, it is best known for the dancers' swinging side to side hip movements. It became internationally popular in the early twentieth century.

Paso Doble.

A moderately fast two-step South American dance of the 20th century. (Spanish for 'double step').

Conga.

Afro-Cuban dance which became popular in America and Paris during the 1930s. It consists of three steps forward followed by a kick. Although it can be danced solo or by a couple, it is best known as performed by a single-file column of people zigzagging around the room, each person holding on to the hips of the person in front.

Mambo

Cuban dance invented in the late 1930s by the double-bass player, Israel 'Cachao' López, by speeding up and syncopating older Cuban dance styles.

Salsa.

A comprehensive term for dances of shared Cuban and Afro-American origins.

Samba.

Of Brazilian origin, it became popular in western Europe and the United States in the 1940s. It has simple forward and backward steps and rocking body movements and is danced to syncopated 4/4 time music.

Swing.

A generic term for American dances emanating from the North American swing jazz movement, such as the lindy hop, jitterbug and jive. (*See below*).

Lindy Hop.

The first and most athletic form of swing dancing, performed by black dancers in the United States and believed to be named after Lindbergh's flight across the Atlantic in 1927. Born in 1928 during a dance marathon of the Depression when one of the contestants broke away from his partner to improvise solo steps, it was the first dance in which couples began to 'do their own thing'. In the dance halls of Harlem it became increasingly flamboyant, with spinning, jumping, and throwing partners around.

The style died out with the advent of the Twist but there was a revival in Britain and America in the 1980s and 1990s, led by companies such as the Jiving Lindy Hoppers of London.

Jitterbug.

A form of swing dancing. Basically the lindy hop which had become popular with white dancers in America during the 'swing era' of the 1930s, producing a slightly less acrobatic, more refined variation. The jitterbug was popular in Europe during and immediately after the Second World War, having been brought over by American servicemen.

Boogie-woogie.

An Afro-American dance in which the dancer moves forward with knees together and hips swaying from side to side. It developed in the 1940s with the rise of boogie-woogie music, and was basically a modified version of the lindy hop to suit faster music.

Jive.

Based on the swing dancing brought to Europe in the 1940s, jive was its most popular form at the start of the rock and roll era. Today it is the form of competitive swing dancing internationally recognised. A simpler form, Modern Jive, arose in the 1980s. This has also been known as Ceroc, LeRoc or French Jive.

Rock'n'Roll.

Originally the dance performed to the rock and roll music of the 1950s, and evolved from the lindy hop and boogie-woogie into an even more athletic dance. It was popularised by the American band leader Bill Haley (1925–81), in particular with his number *Rock Around the Clock* in 1953. It is now a choreographed acrobatic dance designed for stage or competition performance by couples or groups.

Cha-Cha-Cha.

A variant of the mambo which was popular in the 1950s. The basic movement is three steps followed by a shuffle. Created by the Cuban composer Enrique Jorrín.

Bossa Nova.

A lively Brazilian dance of the late 1950s in syncopated 2/4 time, similar to the samba. Bossa nova music was a fusion of the samba and jazz. The name is from the Portuguese *bossa*, trend, and *nova*, new.

Merengue.

Originating in the Dominican Republic and Haiti, it became popular as a ballroom dance in the United States in the 1950s and 1970s. A couple dance to music in 4/4 time, it is danced with a 'limp' step, the weight being always on the same foot.

Twist.

A lively non-touching dance of the early 1960s which is performed on the spot by rocking with bent knees from side to side and up and down while twisting the body. It was made famous by the Chubby Checker song of the same name in 1960, and was deemed socially acceptable for all, coming as it did after the more outrageous rock'n'roll dances performed by teenagers.

Reggae.

Strongly accentuated off-beat dance, originating in Jamaica in the mid-1960s. The name probably comes from the Jamaican/English *rege-rege*, ragged clothing. *See also* **P26**.

Disco Dancing.

Freestyle modern dance with exaggerated hand and arm movements, popularised by the film *Saturday Night Fever* (1977).

Hip-hop.

Originating in New York during the late 1960s as part of a generalised Hispanic and Afro-American hip-hop culture, which included rap, hip-hop dance styles mainly comprise breakdance and body-popping. The latter consists of robotic move-and-freeze actions of the joints in quick succession giving the dancer a mechanical appearance.

Breakdancing.

A street dance style from the hip-hop culture of the South Bronx, New York City, in the 1970s. Acrobatic and energetic, it is characterised by fast footwork and body spins ending in a 'freeze' position. The name relates to the original music for the dance, which consisted of repetitions of a percussion 'break' extracted from a musical number and strung together by the DJ.

DANCE AS SHOW BUSINESS.

In almost all its guises dance is meant to be watched as well as performed. Even religious dance often assumes a spectator. The explosion in the entertainment industry in America and Europe from the later nineteenth century onwards inevitably extended to dance, and one of its most obvious and popular manifestations is tap dance.

Tap Dance.

In tap dancing the dancer wears shoes fitted with small metal plates under the toe and heel in order to produce audible beats from the foot rhythmically striking the floor. This style of dance evolved during the nineteenth century in the United States, principally from an amalgamation of the Irish jig, the Lancashire clog dance and African tribal dances. Initially the shoes for the resulting dance style (known as 'soft shoe') did not have metal taps; these were introduced later when the style evolved through various stages into modern rhythm tap, which became the most popular form of stage dancing during the first thirty years of the twentieth century. Among its well-known exponents were Fred Astaire, Ginger Rogers and Gene Kelly.

In the twenty-first century, it is exerting growing attraction on amateur dancers.

Ballet.

Dance as high art in the western world, however, is represented by the highly disciplined and sophisticated art of ballet. Ballet combines dance with the arts of music and painting to tell a story or create an atmosphere. The music must be closely linked with the dance in tempo and spirit, and the art of the painter is employed in creating the decorative background and the costumes.

(i) Origins.

Ballet is a comparatively young art, with its origins in the revival in fifteenth-century Italy of the art of pantomime, which had been popular in Roman times. This was an entertainment where a story was mimed while a chorus sang or declaimed the action of the scene. The earliest recorded entertainment of this kind was in 1489, to celebrate the marriage of the Duke of Milan. A century later Catherine de Medici, the widow of the king of France, introduced this style of entertainment to the French court, where in 1581 the first recorded instance of dance and music arranged in a coherent dramatic form was composed, the *Ballet Comique de la Reyne*. The male and female characters were all played by men and the ladies of the court supplied the chorus, the *corps de ballet*. For many years ballet remained popular with succeeding French kings, who often took part in them themselves, culminating in the founding of *L'Académie Royale de Musique et de Danse* in 1661 by Louis XIV. Towards the end of the seventeenth century ballet moved from the court to the stage and women were no longer confined to the *corps de ballet*, although they were still the ladies of the court until the first appearance of a professional dancer in 1721. When Marie Taglioni appeared in *La Sylphide* at the Paris Opéra in 1832 it heralded the era of Romantic ballet and the adulation of the ballerina at the expense of the other aspects of ballet. The only true surviving ballet from this period is *Giselle*.

(ii) Ballet in Russia.

The first academy of dancing had been founded in 1735 and an Imperial Ballet School established in St Petersburg in 1775. At first the influence of Paris was strong, with a succession of ballet masters from there coming to Russia, until one, arriving in St Petersburg in 1801, encouraged the development of a Russian ballet tradition by incorporating their own national dances.

It was in St Petersburg after 1862 that the revival of ballet as an artistic unity occurred, where Marius Petipa worked closely with composers of the music. The great classical ballets with music by Tchaikovsky were produced at this time. The next stage in the development of ballet was due to the great impresario Diaghilev, who gathered around him some of the greatest dancers, musicians and artists of the time – including notably, at various times, Stravinsky as composer and Picasso as designer of backdrops – to create exciting new ballets which he brought to Paris in 1909 and London in 1911. Their success revolutionised ballet everywhere except in Russia, which continued with the classical tradition.

(iii) Ballet in England.

The foundations of ballet in England were laid by two women who had both worked in Diaghilev's company: Marie Rambert as a teacher and Ninette de Valois as a dancer. They created the Ballet Rambert company and the Vic-Wells Company respectively, the forerunners of the modern ballet companies, notably the Royal Ballet.

THE CINEMA

This section provides a brief but wide-ranging introduction to the world of the cinema. It includes sections on how the cinema has evolved, entries on many famous directors, actors and actresses as well as a wide-ranging glossary of key film terms (from cult movie to Hollywood Ten and Ealing comedy). There is also a list of major Oscar Winners.

THE CINEMA

1. THE EVOLUTION OF THE CINEMA

THE HISTORICAL BACKGROUND

The Lumière Brothers

It was in December 1895 that the Lumière brothers, Louis and Auguste, organised what is generally regarded as the first exhibition of "moving pictures" for admission money. The event was really the culmination of numerous photographic developments that had taken place over the preceeding decades. These included Eadweard Muybridge's famous photographs of horses in motion in 1871; Etienne Julius Marey's development of a so-called "photographic rifle" with which he could take ten pictures a second (the term "shooting" for a film is commonly thought to derive from this); George Eastman's launch in 1888 of the Kodak camera and his development of the celluloid roll film; and Thomas Edison's production in 1891 of the 35mm film and, with his brilliant assistant W.K.L. Dickson, the later development of the Kinetoscope which showed photographic moving pictures in a peepshow.

Georges Méliès

The Lumière brothers owned a factory that manufactured cameras and photographic equipment and envisaged the motion picture primarily as an extension and promotion of this. Their work, mostly documentary with a number of comic or light dramatic set-pieces, is seen as a major precursor of realism in the cinema. Roughly contemporary with them was the stage magician, Georges Méliès who made the first trick films, using a variety of artificial devices and special effects to tell entertaining science and pseudo-historic tales. In some ways, the Lumierès and Méliès exemplify the two major tendencies to which the cinema has been drawn throughout its history: film as magic carpet (the Méliès tradition) or film as window on the world (the Lumière tradition), film as dream or film as document.

The Coming of Sound

Despite many innovations (such as three-dimensional cinema, which has made a recent comeback, the technical battery of cinema has remained in many respects remarkably moderate. Special effects, the development of sophisticated animation techniques, quadrophonic sound in certain large city-centre cinemas, and an increasingly sophisticated range of colour techniques are all quantitative rather than qualitative modifications, and plans to enlarge the sensory battery of cinema through pumping appropriate scents in the cinema (and even providing spectators with suitable tactile stimuli) have never developed in any sustained way. The major date in the history of the medium remains 1927, the year of the first sound film (*The Jazz Singer*, with Al Jolson).

Sound was fiercely resisted (by Charlie Chaplin among others), but its possibilities were so rapidly recognised, not least by Rene Clair and Alfred Hitchcock who both made early innovatory use of it, that its survival was never long in jeopardy.

Introduction of Colour

As well as sound, another major technical development was in colour photography. Film prints had been tinted from the earliest days (a fact worth bearing in mind when it is sometimes assumed that all silent films were monochrome) but colour of a high technical standard did not become widely used until after the Second World War. Colour first tended to be used for fantasy or adventure genres or spectaculars such as *Gone With the Wind* (1939), and it was not until the mid 1960s that sales of film to television more or less demanded that every film be made in colour. Nevertheless, there are a number of films that continue to be filmed in black and white, not out of a hostility to colour, but for purposes of, for example, nostalgia (as in Woody Allen's *Manhattan*, 1979 or *Purple Rose of Cairo*, 1985), brutal realism (Scorsese's *Raging Bull*, 1980), pastiche and homage (Tim Burton's *Ed Wood*, 1994) and of dramatic newsreel evocation (as in Spielberg's *Schindler's List* of 1993, with its momentary bursts of colour). A recent example is George Clooney's film about the McCarthyist era, *Good Night and Good Luck* (2005). Colour has also often been used expressively: for example, to evoke a mood (as in Antonioni's *Red Desert* of 1964) or as dramatic motif (the menacing use of red in Nicolas Roeg's *Don't Look Now* of 1973) or to suggest a process of ironic distancing from a set of stylistic conventions (as with the deliberately lurid colours in Douglas Sirk's melodramas).

Although its use has sometimes been unimaginative and blandly naturalistic, colour has become a rich and important part of cinematic language and it has been shown that it can co-exist with black and white, sometimes even in the same film.

The Coming of the Big Screen

Another technical development was that of the big screen—in processes such as Cinerama, Cinemascope, Todd-AO—particularly associated with the fifties and sixties, when Hollywood's response to the threat of television was not necessarily to make movies better but at least to make them wider. Many directors hated this development, feeling that the new screen shape was only suitable for filming duck-shoots or dachshunds and not permitting the kind of concentrated detail a director had formerly required. "You can't get a close-up of a finger nail," commented Alfred Hitchcock disdainfully. Nevertheless, a director like Nicholas Ray (who had noted that every technical advance of the cinema had generally been greeted with dismay) demonstrated in a film like *Rebel Without a Cause* (1955) that it was possible to use colour and widescreen for eloquently expressive purposes. A film like Kenneth Branagh's *Hamlet* (1997) was made in 70mm in an attempt to emulate the visual splendour of epics of three decades earlier, such as *Lawrence of Arabia* (1962).

Computer Animation

In recent years, video technology had made it more possible for new film-makers to engage in comparatively inexpensive, independent and experimental work: experienced directors such as Antonioni, Godard and Chris Marker have also made use of this. But the major advances in the last two decades have been in the area of special effects as generated by new technologies of computer animation. These have brought new virtuosity into the realm of the Disney cartoon; new visual wonders into spectaculars such as *Jurassic Park* (1993), *Men in Black* (1997) and *Gladiator* (2000); and fresh tricks of illusion in their capacity seamlessly to blend live-action and animation or computer re-touching, as seen in the films of Robert Zemeckis such as *Who Framed Roger Rabbit* (1988) and *Forrest Gump* (1994).

The downside of this is the danger that technology for its own sake might come to overwhelm narrative, characterisation, artistic creativity: precisely those qualities which made cinema not simply one of the technological wonders of the twentieth century but its major new art form.

MAJOR DATES AND THEIR SIGNIFICANCE

1895

On 28 December, the Lumière brothers gave the first paying show of films, at the Grand Café in Paris—a programme of documentary and comedy shorts.

1896

2 February—the Lumière programme screened at the Regent Street Polytechnic in London, the first film-show in Britain. Later that year, the British film pioneer, R. W. Paul made a celebrated film of the Derby.

1903

Edwin S. Porter made the most famous of all early silent films, *The Great Train Robbery*, credited as being the first Western and the first film to tell a story. Porter was later to direct a film called *Rescued From an Eagle's Nest* (1907), the leading role being taken by a young actor called Lawrence Griffith who was later to change his initials to DW and his profession to director.

1909

The theatrical producers Klaw and Erlanger forbade their contracted actors to appear in films—a sign both of the way theatre looked down on the movies but also feared their competition.

1910

D. W. Griffith made a film in California, partly to avoid the prohibitive actions against independents by the New York based Motion Pictures Patent Company and partly because of the more favourable climate for filming. It marked the beginning of what was to become Hollywood.

1911

The first fan magazines, *Motion Picture Story Magazine* and *Photoplay* began publication in the USA. The era of the star was about to emerge, particularly when, in an elaborate publicity stunt, the independent producer Carl Laemmle revealed the identity of the 'Biograph girl' as Florence Lawrence.

1912

Adolph Zukor established the Famous Plays Film Company and had a big success with the distribution of *Queen Elizabeth* starring the legendary Sarah Bernhardt. "Mister Zukor," she told him, "you have put the best of me in pickle for all time."

1913

Mack Sennett made his first films from Keystone studios.

1914

The release of the first Chaplin film, *Making a Living*. His first appearance as the Tramp occurred shortly after in *Kid Auto Races at Venice*.

1916

The release of D. W. Griffith's *Intolerance*, whose narrative and technique baffled early audiences but which was to prove an enormous influence on future film makers, such as Eisenstein and Pudovkin.

1917

Chaplin signed a million dollar contract making him the highest paid screen star up to this point.

1919

United Artists formed, with Chaplin, Mary Pickford, Douglas Fairbanks and D. W. Griffiths as partners.

1921

Roscoe "Fatty" Arbuckle was charged with the rape and murder of Virginia Rappe. Although later acquitted on all charges, his career never recovered and it was one of several scandals to rock Hollywood in the early 1920s—*e.g.* the unsolved murder of the director William Desmond Taylor in 1922, the death through morphine addiction of the actor Wallace Reid in 1923. The Arbuckle scandal "drew the lightning on us all," said Gloria Swanson: it reflected the sometimes morbid fascination of the public and the press with film stars that was later to become recognised as part of the price of fame and to have an impact on the development of some film careers (*e.g.* Chaplin, Ingrid Bergman, Marilyn Monroe).

1922

Lenin told the People's Commissar for Education: "Of all the arts, for us cinema is the most important." Robert Flaherty makes *Nanook of the North*, often seen as the first great documentary film.

1925

Director Mauritz Stiller and actress Greta Garbo left Sweden for Hollywood. The year of Eisenstein's film, *The Battleship Potemkin*, revolutionary in both theme and technique.

1927

The dawn of sound. Al Jolson's "You ain't heard nothing yet" in *The Jazz Singer*, were the first words spoken on a film soundtrack.

1928

Mickey Mouse made his first appearance in *Plane Crazy*.

1929

The Great Depression hit the American stock market, but cinema proved resilient.

1933

Following Adolf Hitler's rise to power, Joseph Goebbels became Minister for Information in Germany and assumed total control over the national cinema. Acclaimed director of *Metropolis* (1926) and *M* (1931), Fritz Lang was invited to become head of the national film industry: instead he emigrated to America.

1936

Hollywood's Anti-Nazi League was founded, foremost amongst its members being Dorothy Parker, Fritz Lang and Fredric March. (A decade later the League will be denounced by the newly constituted House UnAmerican Activities Committee as a Communist front.)

1938

Former child star Jackie Coogan (immortalised in Chaplin's *The Kid* of 1921) sued his mother and stepfather for the recovery of earnings in his period of popularity. He won the case but the money was swallowed up in legal costs. (Fifty years on, star of *Home Alone* Macaulay Culkin would experience not dissimilar problems).

1939

The outbreak of the Second World War was marked by the banning of Renoir's *La Règle du Jeu* in France and the departure of many European directors for Hollywood. Fritz Lang had already left; Renoir left France in 1940. A golden year for Hollywood cinema, culminating in the huge success of *Gone with the Wind*.

1940

Tom and Jerry appeared in their first movie, *Puss gets the Boot* and Bugs Bunny asked "What's up, Doc?" in *A Wild Hare*. Meanwhile the British Ministry of Information took over the GPO Film Unit and proceeded to sponsor a major series of wartime documentaries.

1941

Germany invaded Russia, and the entire Soviet industry turned itself over to the war effort. In Hollywood there were two remarkable directing debuts: Orson Welles's *Citizen Kane* and John Huston's *The Maltese Falcon*.

1942

First use of the term "neo-realism" by the Italian critic Umberto Barbaro. Marcel Carné began work on *Les Enfants du Paradis* which took three years to make. One of the reasons for this was that it kept cast and production-team away from the fighting.

1946

The opening of the first Cannes Film Festival—originally planned for 1939 but postponed on account of the war. The peak year for box-office attendance in America (4,500 million entries)..

1947

The US House UnAmerican Activities Committee (HUAC) began hearings in Los Angeles to root out "Communists" (*i.e.* liberals) in the industry. The investigation, begun on 18 October, wreaked enormous personal, financial, and artistic havoc. Cheryl Crawford, Elia Kazan and Lee Strasberg opened the Actors' Studio (home of 'The Method') in New York.

1948

French critic Alexandre Astruc predicted that the cinema would become "a means of writing just as flexible and subtle as written language", in an article that would have a tremendous impact on the French *Nouvelle Vague* directors.

1949

The release of Henry Cornelius's *Passport to Pimlico*, Alexander Mackendrick's *Whisky Galore* and Robert Hamer's *Kind Hearts and Coronets* highlighted a series of distinctive films emanating from Michael Balcon's Ealing Studios, whose humour and superb cast of character-actors ensured their success until the last of the great comedies (*The Ladykillers*) six years later.

1951

Akira Kurosawa's *Rashomon* won the Golden Lion at the Venice Film Festival, introducing the West to Japanese cinema.

1952

Charlie Chaplin, in England for his film *Limelight*, learned his re-entry permit to America had been rescinded, beginning a twenty year period of exile from that country. Twentieth Century Fox announced the imminent launching of their new wide screen system, Cinemascope. 3-D was invented, one of its successes being *House of Wax*, directed by the one-eyed Andre De Toth.

1956

Satyajit Ray's *Pather Panchali* won a major award at the Cannes Festival, although a young French critic walked out of the screening declaring he was not interested in a film about Indian peasants: his name was Francois Truffaut.

1959

Francois Truffaut's *Les Quatre Cents Coups* and Godard's *Breathless* inaugurated what came to be known as the French *Nouvelle Vague*.

1960

Kirk Douglas (with *Spartacus*) and Otto Preminger (with *Exodus*) effectively ended the "anti-communist" blacklist when they employed as screenwriter the formerly blacklisted Dalton Trumbo. Antonioni's *L'Avventura* was noisily barracked at the Cannes Film Festival: within eighteen months, he was to be the most fashionable and esteemed director in Europe.

1961

Luis Buñuel invited to return to Spain; he did so with *Viridiana*, infuriating the Franco régime.

1968

Cannes Film Festival ended abruptly when there were demonstrations in support of student protests. In America, the youth rebellion movie of the fifties took on a new lease of life, culminating in the success of Dennis Hopper's *Easy Rider* (1969).

1975

Steven Spielberg had a huge box-office success with *Jaws*, to be topped two years later by his friend and fellow "movie brat" George Lucas, with *Star Wars*.

1987

Bernardo Bertolucci's *The Last Emperor* is the first Western film to be shot in Beijing. It coincided with a new Western interest in Chinese film.

1988

Krzysztof Kieslowski's *A Short Film About Killing* (U.S. title: *Thou Shalt Not Kill*) was voted best film at the first European Film Awards.

1996

Mike Leigh's *Secrets and Lies* won the Golden Palm at the Cannes Film Festival and the director celebrated his victory as a comeback for the modestly priced film that deals with human values. By way of contrast, a Hollywood epic about alien invasion, *Independence Day*—a B-picture in all but inflated cost and special effects grandeur—became the box-office blockbuster of the summer. The death of Krzysztof Kieslowski.

1998

The death of director Akira Kurosawa, one of the giants of post-war cinema. The success of Spielberg's *Saving Private Ryan* sparks a new interest in films about World War Two.

1999

Box office success of *Shakespeare in Love* which goes on to win 7 Oscars. Death of Japanese film-maker Keisuke Kinoshita.

2000

British theatre director Sam Mendes wins an Oscar for his first film, *American Beauty*. Meanwhile two of the major European talents of the 1990s, Spain's Pedro Almodovar and Denmark's Lars von Trier are also rewarded. Almodovar's *All About My Mother* wins the best foreign film Oscar; Von Trier's *Dancer in the Dark* controversially wins the Golden Palm at Cannes.

2001

Death of American film producer/director Stanley Kramer whose films as producer included *The Wild One* and *High Noon*. Ang Lee makes a huge crossover success, an arthouse martial arts movie, *Crouching Tiger, Hidden Dragon*, that wins four Oscars. Steven Spielberg completes *A.I.*

2004

Lord of the Rings: Return of the King triumphs at Oscars. Mel Gibson's *The Passion of the Christ* is a huge success.

2007

Dame Helen Mirren wins Best Actress Oscar for her role in *The Queen*. (First British actress to win this award since Emma Thompson in 1992). Deaths of two towering giants of European cinema, Michelangelo Antonioni and Ingmar Bergman.

2008

Deaths of Oscar-winning directors Anthony Minghella and Sydney Pollock.

2009

Triumph for *Slumdog Millionaire* (taking 8 Oscars); Kate Winslet finally wins coveted Best Actress award.

2010

Death of French New Wave director Eric Rohmer, best-known for *My Night at Maud's* and *Claire's Knee*. *Avatar* becomes the biggest grossing film of all time (surpassing James Cameron's other huge hit, *Titanic*). Death of Chabrol.

2011

Triumph for *The King's Speech* at the Oscars in February 2011. Death of screen legend Elizabeth Taylor. Other deaths in 2011 included Ken Russell, Susannah York and Bollywood legend Dev Anand.

2012

Deaths of film producers Richard Zanuck and Tony Scott (whose films included *Top Gun*).

2013

Bollywood celebrates its centenary. Daniel Day-Lewis wins record third Best Actor at Oscars. Deaths of Bryan Forbes and Peter O'Toole.

2014

Death of Shirley Temple, Hollywood's favourite child actress. Deaths of Mickey Rooney, Robin Williams and Lauren Bacall.

2015

Death of Mike Nichols, Oscar-winning director of *The Graduate* (1967) *Frozen* becomes the highest grossing animated film of all time. *Volte face* by Sony Pictures over *The Interview*. Deaths of Omar Sharif, Anita Ekberg (famous for *La Dolce Vita*), Sam Goldwyn Jr. and Maureen O'Hara

2016

Deaths of Robert Vaughn, Gene Wilder, Zsa Zsa Gabor (better known for her nine marriages) and Debbie Reynolds.

2017

Fiasco over best picture. Mahershala Ali becomes first Muslim actor to win an Oscar.

2. THE LEADING CINEMA DIRECTORS

Allen, Woody (b. 1935)

Woody Allen first achieved star status as an actor in movies he himself directed, playing a walking worry-bead who wore his urban anxiety like a red badge of courage. Films like *Take the Money and Run* (1969), *Bananas* (1971) and *Love and Death* (1975) seemed to align him with prior film farceurs like his favourite, Bob Hope. He became more ambitious and intellectual, with films such as *Annie Hall* (1977) and *Stardust Memories* (1980) being anguished as well as amusing self-portraits, and *Interiors* (1978) being a study of family breakdown closer to Chekhov than Chaplin. Films such as *Zelig* (1983) and *The Purple Rose of Cairo* (1985) have shown him to be the technical equal of any contemporary American director, whilst *Hannah and her Sisters* (1986) and *Crimes and Misdemeanours* (1989) have the philosophical density of a Russian novel.

However, after *Husbands and Wives* (1992) and a bitter and much publicised split with his partner Mia Farrow, he has returned to comedy, spicing the humour with considerable formal adventurousness for a dwindling but loyal following. A film made in Britain, *Match Point* (2005) was his most acclaimed in years, unlike *Cassandra's Dream* (2007).

Almodovar, Pedro (b. 1951)

Almodovar came to international attention with *Women on the Verge of a Nervous Breakdown* (1988), which won numerous awards and was a typical example of what has since been called "Almodrama"—emotionally extravagant and sexually outrageous stories that revel in passionate extremes and narrative quirkiness. A film-maker of the post-Franco era whose work has tended to ignore or reject his country's political past, Almodovar's recent films have shown a new depth and compassion in their exploration of the hidden by-ways of love. *Talk to Her* (2002) won him a best screenwriting Oscar. Other key films: *Matador* (1986), *Tie Me Up! Tie Me Down!* (1990), *High Heels* (1991), *Live Flesh* (1998), *All About My Mother* (1999), *Bad Education* (2004), *Volver* (2006), *The Skin I live in* (2011) and, most recently, *Live Flesh* (2015).

Altman, Robert (1925–2006)

Innovative, iconoclastic director who shot to prominence with the military comedy *M:A:S:H* (1970), and then proceeded to subvert some of America's major film genres, notably in his western *McCabe and Mrs. Miller* (1971), which was more about the rise of capitalism than the growth of civilisation, and in his private-eye movie, *The Long Goodbye* (1973), where he debunked Raymond Chandler's knight-errant hero, Philip Marlowe. His epic and ironic fresco on the American Dream, *Nashville* (1975) was a highpoint of his career. After that he became ever more esoteric and experimental. Nevertheless, in films like his imaginative realisation of the play, *Come Back to the Five and Dime, Jimmy Dean, Jimmy Dean* (1982), and the made-for-TV biopic of Van Gogh, *Vincent and Theo* (1990), he showed he could still spring some surprises.

His Hollywood satire, *The Player* (1992) was his most acclaimed film for a decade; his ambitious adaptation of Raymond Carver short stories, *Short Cuts* (1994) was no less impressive; and his country house satire *Gosford Park* (2001) was both a critical and commercial success. He was awarded an honorary Oscar in 2006.

Antonioni, Michelangelo (1912–2007)

Antonioni was the director who made alienation fashionable in the early 1960s with his trilogy *L'Avventura* (1960), *La Notte* (1961) and *The Eclipse* (1962), which explored the gap between his characters' material affluence and their spiritual impoverishment. He also gave alienation a palpable visual form, each shot an eloquent comment on the tension between protagonist and environment.

These films remain his greatest achievement, and in Monica Vitti he found a leading lady whose haunted performances greatly enhanced the emotional impact of his work. His other major films include *Le Amiche—The Girl Friends* (1955), *The Red Desert* (1964), *Blow-Up* (1966) and *The Passenger* (1975).

Bergman, Ingmar (1918–2007)

The definitive example of the film artist, by virtue of the maturity and complexity of his themes and of the control he had over all aspects of his films—writing, casting *etc.* Since he established his international reputation with a trio of masterly works in the 1950s—*Smiles of a Summer Night* (1955), *The Seventh Seal* (1956) and *Wild Strawberries* (1957)—he enjoyed almost complete creative freedom. Films like *The Seventh Seal*, *Through a Glass Darkly* (1960) and *Winter Light* (1962) test the validity of an individual's religious faith in a world of fearful cruelty, whilst a masterpiece like *Persona* (1966) is a revelatory study of character and creativity, superbly acted by Bibi Andersson and Liv Ullmann. There are those who criticise Bergman for the narrowness of his social range, his limited political vision, his spiritual masochism. But to Bergman the camera eye was the window of the soul and few have probed more deeply to the roots of human personality. And it is not all Scandinavian gloom. In *Fanny and Alexander* (1983), he created a wonderful reminder of his story-telling gifts, his rich visual sense, and his capacity to embrace life with all its pain, perils, and pleasures.

Bergman's autobiography, *The Magic Lantern* was published in 1988; and his screenplay about the early life of his parents, *Best Intentions* (1992) was memorably filmed by Bille August. Another screenplay, *Faithless* (2000) has been directed by Liv Ullmann and he himself returned to direction with *Sarabande* (2005).

Bertolucci, Bernardo (b. 1940)

The Italian Communist Party evolved in the seventies the conception of the "historic compromise"—a tactical alliance on the part of a self-styled revolutionary party with progressive reformist forces. Bertolucci's aesthetic strategy can be seen as an (unconscious?) embodiment of this—a "message" of revolution often clothed in the glossy, star-studded forms of bourgeois Hollywood cinema, as in the two-part *1900* of 1976. Likewise, in *Last Tango in Paris* (1972), the brutal sexual frankness for which the film rapidly became notorious is cushioned by the reassuring Hollywood deep-orange glow in which the scenes are shot and the presence of attested Hollywood rebel Marlon Brando. He won an Oscar for the opulent epic, *The Last Emperor* (1987), and *The Dreamers* (2003) was a return to form, but his best films are his early works—*Before the Revolution* (1964), *The Spider's Stratagem* (1970), *The Conformist* (1970)—which combine an incisive political and psychological analysis with a poetic and lyrical style.

Brooks, Richard (1912–92)

Leading writer-director of the postwar American cinema. Author of the novel on which the film *Crossfire* (1947) was based and co-writer on Huston's powerful allegory *Key Largo* (1948), Brooks made his directing debut in 1950 and became a specialist in accessible, highly charged adaptations of literary classics. His best film is *Elmer Gantry* (1960), an incisive dissection of American evangelism that won Oscars for Brooks (as screenwriter) and its star, Burt Lancaster and features the characteristic Brooks protagonist: a dynamic, divided individualist treading a tightrope between redemption and damnation. Key films: *Blackboard Jungle* (1955), *Cat on a Hot Tin Roof* (1958), *Sweet Bird of Youth* (1962), *Lord Jim* (1965), *The Professionals* (1966), *In Cold Blood* (1967).

Buñuel, Luis (1900–83)

Buñuel began his career by collaborating with Salvador Dali on a surrealist short, *Un Chien Andalou* (1928) and then scandalised audiences with *L'Age d'Or* (1930), which attacked the Church ("Thank God I'm an atheist", Buñuel declared) and bourgeois morality (which Buñuel always found deeply immoral). A powerful, hallucinatory film about violence and poverty in the slums, *Los Olvidados* (1950) launched a second phase of his career, and his religious assaults were continued in *El* (1953), which equated religious orthodoxy with emotional repression, and *Nazarin* (1958) and *Viridiana* (1961), which showed the impossibility of a modern Christ surviving in today's society. In his final years, he took pleasure not so much in savaging the bourgeoisie as in, metaphorically speaking, poisoning their food, serving them a dainty cultural dish with a sinister undertaste. *Belle de Jour* (1967), *Tristana* (1970) and *The Discreet Charm of the Bourgeoisie* (1972) are all slyly subversive, surreal works, dealing with the split between appearance and reality, decorum and desire. He believed man was unconsciously a slave to custom and to social orthodoxy and, with his enthusiasm for symbols and the world of dreams, which reveal the hidden fears and desires of modern man, Buñuel did everything in his power to shock man out of his complacency. His impish spirit was also revealed in his appropriately liberating autobiography, *My Last Breath*, published in 1983.

Capra, Frank (1897–1991)

The films of Sicilian-born Frank Capra embodied the American Dream. His major works were comedies with a strong moral lesson, and their message of optimism over adversity cheered up audiences during the Depression. His films were essentially variations on David and Goliath, with the common man victorious over seemingly insurmountable odds. His main characters, such as Gary Cooper's Mr. Deeds in *Mr. Deeds Goes To Town* (1936) or James Stewart's Mr. Smith in *Mr Smith Goes to Washington* (1939) were innocent idealists who vanquished the cynical, the crooked and the corrupt. After winning three directing Oscars in the 1930s, Capra never recovered his popularity after World War Two and retired after *A Pocketful of Miracles* in 1961. His testament is the aptly entitled *It's A Wonderful Life* (1946), a beautiful fantasy, with dark undertones.

Carné, Marcel (1909–96)

Carné occupied a role in the immediately pre-war cinema in many ways similar to that of Antonioni in the early sixties—the poet of an age's style of despair, whose fatalism receives tangible support and embodiment from the skilful use of decor and architecture. In Carné's case these were entirely studio-bound (his mature masterpieces eschewed location filming entirely), which may be one reason why his output has dated compared with, say, Renoir's. But *Quai des Brumes* (1938) and *Le Jour Se Leve* (1939) provide atmospheric frameworks for the acting of Jean Gabin, and *Les Enfants du Paradis* (1945), the three-and-a-half-hour tale of lost love and cynicism in the theatrical world of nineteenth-century Paris, remains exciting through its amalgam of "period" style and a tortured consciousness evocative of the time at which it was made. With Rene Clement (director of *Jeux Interdits*, 1952) and Henri-Georges Clouzot (maker of *Wages of Fear*, 1952 and *Les Diaboliques*, 1955) Carné fell out of fashion at the time of the less studio-and-script-bound films of the *Nouvelle Vague*, but in 1979, French critics voted *Les Enfants du Paradis* as the best French film ever made.

Cassavettes, John (1929–89)

Actor-director who, with associates such as his actress-wife Gena Rowlands and actor-friends such as Peter Falk and Ben Gazzara, made offbeat films that focused more on intimate relationships than exciting narrative. Improvisational and unashamedly indulgent, the films have been an inspiration to independent film-makers wishing to eschew the mainstream. Films include: *Shadows* (1960), *Faces* (1968), *Husbands* (1970), *A Woman Under the Influence* (1974), *Killing of a Chinese Bookie* (1976), *Love Streams* (1982).

Chabrol, Claude (1930–2010)

Like Godard and Truffaut, Chabrol first distinguished himself as an abrasive and articulate critic on the magazine *Cahiers du Cinema* before branching into direction. With Eric Rohmer (later also to become a director), he also wrote an influential book at this time on the films of Alfred Hitchcock. Hitchcock has been a strong influence on Chabrol's films, which are often cynical detective stories or psychological suspense thrillers set against carefully observed French provincial settings. He is a cool anatomist of the discreet charms and deadly passions of the bourgeoisie. His key films include *Les Cousins* (1958), *Les Bonnes Femmes* (1960), *Les Biches* (1968), *La Femme Infidele* (1969), *Killer!—Que la Bete meure* (1969), *Les Noces Rouges* (1973) and his best film, *Le Boucher* (1970). More recent work, such as *Judgment in Stone* (1994), adapted from a novel by Ruth Rendell, and *Merci Pour Le Chocolat* (2000) shows he has lost none of his animosity to the bourgeois nor his capacity to disturb.

Chen, Kaige (b. 1952)

With Zhang Yimou, the leading director of the so-called 'fifth generation' of film makers who graduated from the Beijing Film Academy in 1982, following its re-opening after Mao Tse-Tung's Cultural Revolution. His first film, *Yellow Earth* (1984) made an impact in the West comparable to that of *Rashomon* and *Pather Panchali* in its revelation of a new national cinema, and his reputation was consolidated by *Farewell My Concubine* (1993), which shared the top prize at Cannes with *The Piano* and was nominated for an Oscar. However, his first Hollywood film, *Killing Me Softly* (2002) was widely deemed a soft-porn disaster. Other films: *The Big Parade* (1985), *King of the Children* (1987), *Life on a string* (1991), *Temptress Moon* (1997), *The Emperor and the Assassin* (2000).

Clair, Rene (1898–1981)

The first great European musical director. His early interest in asynchronous sound (*i.e.* that which does not always correspond to what we see going on on the screen) led him to attach equal importance to natural noise and music and to dialogue in his early sound films (such as *Sous les Toits de Paris* of 1930). A delight in dance—the choreographed quality of fights, chases and crowd scenes—permeates his two most successful works, *Le Million* and the simplistic but vivacious satire on industrialisation, *A Nous la Liberté* (both 1931) which greatly influenced Chaplin's *Modern Times*.

Cocteau, Jean (1889–1963)

Cocteau was a poet who expressed himself variously in fiction, drama, painting and drawing as well as through the cinema. *Beauty and the Beast* (1946) was an imaginative telling of the familiar tale, with Jean Marais both frightening and poignant as the Beast. In *Orphée* of 1950 he produced one of the cinema's unquestioned fantastic masterpieces, using mirrors as links between the world of the living and that of the dead to great effect, and playing upon the connection between love and death in a way that must have influenced the makers of *Last Year in Marienbad* (Resnais and Robbe-Grillet) eleven years later.

Coen, Joel (b. 1958)

With his brother Ethan (who co-writes and produces), Joel Coen has fashioned some of the most original modern American films, darkly comic, densely plotted dramas that blend passion with pastiche. Their acclaimed film, *No Country for Old Men* (2007) won the Oscar for best film. Key films: *Blood Simple* (1983), *Raising Arizona* (1987), *Miller's Crossing* (1990), *Barton Fink* (1991), *Fargo* (1996), *O Brother, Where Art Thou* (2000), *The Man Who Wasn't There* (2001).

Coppola, Francis Ford (b. 1939)

The Godfather of modern American cinema, confidante and father-figure to the new generation of directors (such as George Lucas and Steven Spielberg) who emerged from film school to storm Hollywood in the early 1970s. Coppola's *The Godfather* (1972) and *The Godfather, Part II* (1974) combined the sweep of a dynastic family melodrama with a mature political analysis of corporate America. The former restored Marlon Brando to superstardom; the latter made stars of Al Pacino and Robert De Niro. Two other major films of the decade were *The Conversation* (1974), a tale of treacherous tapes and an atmosphere of paranoia that evoked Watergate; and *Apocalypse Now* (1979), in which America's incursion into Vietnam was interpreted as a mad, metaphysical journey into the heart of darkness. Since then Coppola has seemed something of a lost soul, searching for inspiration, marking time and, with *Godfather III* (1990) and a revised, extended version of *Apocalypse Now* (premiered at Cannes in 2001) revisiting old haunts. His daughter Sofia is a talented director

Costa Gavras, Constantin (b. 1933)

The cinema's specialist director of the political thriller, throwing up large social issues of corruption and responsibility under the guise of suspense melodrama. He achieved international prominence with *Z* (1969), an indictment of the repressive regime in Greece, and he has had equal success in the mainstream commercial cinema, particularly with *Missing* (1982) and *Music Box* (1989). His film *Amen* (2002), was a typically controversial critique of the Catholic church's failure to attack the Holocaust.

Cronenberg, David (b. 1943)

Canada's most controversial film export, whose early reputation was made with stomach-churning, mind-exploding horror films. Critical respectability came with *The Fly* (1986) and *Dead Ringers* (1988), which married the gore with intellect and compassion, but controversy flared again over his adaptation of J. G. Ballard's notorious novel about eroticism and the automobile, *Crash* (1996). *Spider* (2002) was shown to great acclaim at the Cannes Film Festival. He has had some success with more mainstream films, such as *A History of Violence* (2005) and *Eastern Promises* (2007).

Cukor, George (1899–1983)

Cukor came to Hollywood from directing on the New York stage, and this theatrical background was an important clue to his work. His films were often adaptations of plays, like *Gaslight* (1944); he was always intrigued by theatrical people indulging a flair for the dramatic, either on stage, like Ronald Colman in *A Double Life* (1947), or in a courtroom, like Spencer Tracy and Katherine Hepburn in *Adam's Rib* (1949); and his films are particularly remembered for their performances, *e.g.* Greta Garbo's in *Camille* (1937) or Judy Garland's in *A Star is Born* (1954). Cukor was one of the most civilised of Hollywood directors, versatile and visually stylish, but particularly revelling in the sex-war comedies of Tracy and Hepburn, such as *Adam's Rib* and *Pat and Mike* (1952).

Curtiz, Michael (1888–1962)

Hungarian-born super-professional of Hollywood's heyday. He began his association with Warner Brothers in 1926, making over a hundred films there of every conceivable genre and with stars such as Errol Flynn, James Cagney and Humphrey Bogart. His famous films include *Angels With Dirty Faces* (1938), *Yankee Doodle Dandy* (1942), *Mildred Pierce* (1945) and the immortal *Casablanca* (1943).

De Mille, Cecil B. (1881–1959)

An innovative director in the silent era, Cecil B. De Mille became indelibly associated in his later career with bigness in the movies. His gigantic epics include *The Sign of the Cross* with Charles Laughton in 1932, and two spectacularly tasteless versions of *The Ten Commandments* (1923 and 1956). The films themselves matter less nowadays than the reputation for scale and the consistently successful box-office returns. Joseph L. Mankiewicz observed: "He had his finger up the pulse of America."

De Sica, Vittorio (1902–74)

Although he began his screen career as an actor, Vittorio De Sica is remembered principally for a remarkable group of films he made immediately after World War II, collaborating with writer Cesare Zavattini on works which are regarded as key examples of Italian neo-realism; *Shoeshine* (1946), *Bicycle Thieves* (1948) and *Umberto D* (1952). These sympathetic studies of the poor were heavily criticised in their own country (for political simplemindedness by the Left and for unflattering and unpatriotic portraiture of Italy by the Right) but were widely acclaimed abroad. With the decline of neo-realism in the early 1950s, De Sica was never to scale the same heights, though he did direct Sophia Loren to an Oscar winning performance in *Two Women* (1961), and experienced critical acclaim for two of his final films, *The Garden of the Finzi Continis* (1971) and *A Brief Vacation* (1973).

Dreyer, Carl Theodor (1889–1968)

Dreyer is still regarded as the greatest artist in the history of Danish cinema, though it was in France that he directed his first masterpiece, *The Passion of Joan of Arc* (1928), with its remarkable leading performance by Renee Falconetti in her only screen role. The austerity and apparent Protestant guilt that pervade his work compare interestingly with Robert Bresson's Catholic severity. Dreyer's last film, *Gertrud* (1964) was derided at its premiere, but it is now regarded as one of his finest works, both for its steady satire of the bourgeoisie and its sympathy with women and hatred of their oppression. The slowness of his work still causes difficulty, but the fantastical quality of *Vampyr* (1932), and the undercutting of fanaticism in *Days of Wrath* (1943) and *Ordet/The Word* (1955) are nowadays widely appreciated.

Eisenstein, Sergei (1898–1948)

A prominent theorist as well as practitioner, Eisenstein's Marxist awareness of society as founded upon conflict rather than harmony led him to develop a theory of *montage*, or meaning built up by collision and clash of images. This theory found illustration in what are at the same time highly effective Socialist propaganda films: *The Battleship Potemkin* of 1925, whose massacre-sequence on the steps of the port of Odessa is among the most famous in cinematic history; *October* of 1927 (in which the Menshevik or moderate leader Kerensky is denigrated when his image is followed by that of a peacock—an example of the *montage* technique); and the more contorted and baroque *Ivan the Terrible* (Part one, 1942; Part two, 1945). This last caused Eisenstein to fall into disfavour with Stalin (who may have taken the portrait of the tyrant Ivan to be a reflection upon himself), and the financial difficulties and persecution because of his homosexuality led to his premature death of a heart attack. "Of all the arts", said Lenin, "for us the cinema is the most important". In Soviet Russia its most important voice was Eisenstein who, in finding filmic forms to express collectivism and brotherhood, gave substance to a national ideology.

Fassbinder, Rainer Werner (1946–82)

Phenomenally prolific director of the German cinema of the 1970s, Fassbinder's films at their best combined the political commitment of a Godard with the heady melodrama of a Hollywood director he much admired, Douglas Sirk. His best film is probably *The Marriage of Maria Braun* (1979), an extraordinary allegory of the history of post-war Germany. His best melodramatic films are *The Merchant of Four Seasons* (1972), *The Bitter Tears of Petra von Kant* (1972), *Fear Eats the Soul* (1974) and *Veronika Voss* (1981).

Fellini, Federico (1920–93)

Fellini was an example of the director as star, delighting in treading a thin line between self-expression and self-indulgence. The films recall his early experience in the circus and as a cartoonist, being populated by grotesques and having a unique mixture of risk and spectacle, fantasy and fact. *I Vitelloni* (1953), a semi-autobiographical account of his wastrel adolescent days, established Fellini's reputation; it was enhanced by the international success of his next film, *La Strada* (1954), a parable of body and spirit, love and salvation. With *La Dolce Vita* (1960), a sensational view of contemporary Roman society, Fellini entered his decadent phase, which was to be continued in such films as *Fellini Satyricon* (1969) and *Fellini's Casanova* (1976). His most highly regarded films are his most autobiographical, *8½* (1963), in which a film director encounters a creative crisis and ransacks his past for inspiration, and *Amarcord* (1973) which is a remembrance of his childhood.

Flaherty, Robert (1884–1951)

Often referred to as the "father of film documentary", Flaherty was actually as much a Romantic as a realist. He has been criticised for the political absences in his movies but he was not a polemicist but a poet, making films that were either hymns to a vanishing way of life or recorded elemental struggles between Man and Nature. His best films were his first, and last: respectively, *Nanook of the North* (1922) and *Louisiana Story* (1948).

Ford, John (1895–1973)

"My name's John Ford," he said. "I make Westerns." He not only made them: he transformed them into poetic statements of the American spirit. Particularly celebrated are those he made starring John Wayne: *Stagecoach* (1939), an odyssey of Western outcasts across hostile territory: *The Searchers* (1956), in which Wayne's bitter racialism is eventually tamed; and *The Man Who Shot Liberty Valance* (1962) which pits Wayne against James Stewart. But he also excelled with Henry Fonda (*Drums Along the Mohawk* of 1939), and in non-Western films (*The Grapes of Wrath*, 1940). His greatest limitation is that he is pre-eminently a man's director, whose bourbon-soaked camaraderie and stress on tough, determined action in some of his less successful films palls rapidly. His greatest strengths are as the unsurpassed chronicler of pioneering America and as the sympathetic observer of the endurance of the common people; and his insights into prejudice, injustice and the tragedy of destroyed families. "This is the West, sir", says the newspaper editor of *Liberty Valance*. "When the legend becomes fact, print the legend". Ford printed the legend better than anyone. Other key films: *The Informer* (1935), *The Prisoner of Shark Island* (1936), *How Green Was My Valley* (1941), *My Darling Clementine* (1946), *Fort Apache* (1948) and *The Quiet Man* (1952).

Forman, Milos (b. 1932)

Forman was one of a group of directors of the so-called Czech New Wave of the 1960s, whose comedies such as *A Blonde in Love* (1965) and *The Fireman's Ball* (1967) audaciously satirised authority, both parental and political. In Paris in 1968 when the Soviet tanks rolled into Prague and there was a clampdown on artistic expression, Forman eventually emigrated to America, where he continued to score notable successes with offbeat films, most famously with *One Flew Over the Cuckoo's Nest* (1975) and *Amadeus* (1984).

Fuller, Samuel (1912–97)

A ferocious action director, castigated as neo-Fascist by his adversaries and lauded by his advocates for the tough, unsparing economy and desperate honesty of his work. Fuller worked across different genres, including the spy-thriller (*Pickup on South Street*, 1953) and the Western (*Run of the Arrow*, 1957). In *Shock Corridor* of 1963, his finest and most revelatory work, he combined the investigative-journalist picture with the drama of psychological horror to create an unnerving dissection of American prejudices and fears. His later films were few and far between, though *White Dog* (1983) showed that, given the opportunity, Fuller had lost none of his bite. His was tabloid cinema, done with tremendous verve, admired by modern directors.

Gance, Abel (1889–1981)

"The day of the Image has arrived", proclaimed Abel Gance at the triumphant premiere of his five-and-a-half-hour epic, *Napoleon* (1927), which deployed superimposition, slow-motion, split-screen, colour, and a triple-screen process, Polyvision, that anticipated Cinerama by nearly thirty years. Alas, Gance was mistaken: sound was round the corner and the visual innovations of *Napoleon* were rendered virtually obsolete before they had begun. Not until the film's restoration in 1980 was Gance's achievement appreciated and his own reputation restored as a great innovator of the silent screen.

Godard, Jean-Luc (b. 1930)

"We are the children of Marx and Coca-Cola", claimed Godard in the 1960s, when he seemed the most radical, innovative and controversial director in world cinema. The turning-point was *Weekend* (1967), an apocalyptic black-comedy of chaos and cannibalism, of social and cultural breakdown. From his early films, which were often love letters to the Hollywood cinema, he had moved to an alternative political cinema that seemed to demand not audiences but disciples. His influence on all spheres of alternative, independent, avant-garde film theory and practice continues to be immense. Other key films: *Breathless* (1959), *Vivre sa Vie* (1962), *Le Mepris-Contempt* (1963), *Une Femme Mariee* (1964), *Pierrot le Fou* (1965), *Tout Va Bien* (1972) and *Bridges of Sarajevo* (2014).

Griffith, D. W. (1875–1948)

Griffith more than any other individual was responsible for the cinema moving from short one and two-reelers to the grand epic scale. *The Birth of a Nation* (1915), despite overt racism, was the most exciting attempt the cinema had hitherto made to capture and reconstruct the course of historical events, and broke all box-office records as well as profoundly influencing Eisenstein. Its successor, *Intolerance* (1916), was even more grandiose and cost unimaginable sums by the standards of those days. Apart from *Broken Blossoms* (1919) and *Way Down East* (1920), Griffith's later films were undistinguished and his career ended in a prolonged, drink-sodden decline. Although sometimes criticised for his Victorian melodrama, Griffith is more properly remembered for his popularisation of feature-length narrative; his revelation of the creative possibilities of montage; and his encouragement of a new subtlety and realism in screen performance. He was the first figure to give this new mass medium intellectual respectability.

Hamer, Robert (1911–63)

The problem child of Ealing studios, whose career was to decline due to alcoholism and what producer Michael Balcon was to call Hamer's "self-destructive streak", but who was responsible for at least three classics of British film: "The Haunted Mirror" episode from *Dead of Night* (1945); the neo-realist melodrama about the London underworld, *It Always Rains on Sunday* (1947); and, above all, the black comedy, *Kind Hearts and Coronets* (1949) in which Dennis Price purrs through some of the most suavely literate dialogue in British cinema as he attempts to kill off eight Alec Guinnesses on his way to a dukedom.

Hawks, Howard (1896–1977)

One of the most versatile and consistent operators within the Hollywood studio system. Whatever genre he worked in, it was transmuted and made more ambiguous. Thus the Western *Rio Bravo* (1959) contains a minimum of big-scale outdoor action and a maximum of charged conversation; private-eye classic *The Big Sleep* (1946) is concerned with Bogart's process of ironic self-discovery rather than with who-dunnit (a question to which Hawks himself never worked out the answer); and the action in the civil-aviation drama *Only Angels Have Wings* (1939) takes place predominantly on the ground. His comedies, notably those with Cary Grant, hilariously subvert sex stereotypes, as in *Bringing Up Baby* (1938), *His Girl Friday* (1940) and *I Was a Male War Bride* (1949).

Herzog, Werner (b. 1942)

One of the most exciting of the new German directors in the 1970s, his treatment of madness is particularly penetrating. This is normally undertaken within the context of a part-historical, part-fictional society, as with the paranoia of the sixteenth-century Amazon conquistador in *Aguirre, Wrath of God* (1972), the scandalous insights of the supposed "savage" in *The Enigma of Kaspar Hauser* (1974), and the odd symbiosis between predator and victim in his Murnau remake *Nosferatu the Vampyre* (1978). "Dreams move mountains", says Herzog: it is his philosophy of cinema. Other films: *Grizzly Man* (2005) and *The Bad Lieutenant* (2010).

Hitchcock, Sir Alfred (1899–1980)

For half a century Hitchcock was the acknowledged master of mystery and suspense, whose coldly planned delight in playing on his audience's nerves has occasioned violent disagreement between those who see him as the medium's leading exponent of predestination and those for whom he is but a limited practical joker in bad taste. *Psycho* (1960) remains the most notorious film, less now perhaps for the murder of Janet Leigh in her shower than for the *coup de grace* when the murderer's "real identity" is revealed near the end. *North by North-West* of the previous year is among his most accomplished works, a comic spy-thriller based (like so much that is funniest in Hollywood cinema) on a mistake involving the identity of Cary Grant.

Sexually perverse or tabooed areas which the conventional narrative cinema perforce ignored or treated as marginal assume central (though often implicit) places in his work, *cf.* the latent homosexuality in *Strangers on a Train* (1951), the Grand Guignol parody of an Oedipus complex in *Psycho* and the treatment of repression and the traumatic return of what has been "forgotten" (*i.e.* repressed) in *Marnie* (1964). In recent years his early English films have been revalued and upgraded, and the sexual politics of his films have been analysed. His earliest surviving film, *The White Shadow* (1924) was rediscovered in 2011.

He continues to fascinate because of the multi-sided personality of his work, which reveals at once the mask of a joker of genius, a nihilist, a Catholic moralist, a Freudian sexual psychologist and, in his greatest work, *Vertigo* (1958) an anguished romantic. In 2012, indeed, *Vertigo* was voted the greatest film of all time – a fitting tribute.

Other key films include: *Blackmail* (1929), *The Thirty-Nine Steps* (1935), *Sabotage* (1937), *The Lady Vanishes* (1938), *Rebecca* (1940), *Shadow of a Doubt* (1943), *Notorious* (1946), *Rope* (1948), *Rear Window* (1954) and *The Birds* (1963). For a recent biography, *see* Peter Ackroyd, *Alfred Hitchcock* (2015).

Huston, John (1906–87)

1941 marked two of the most sensationally successful debuts in directorial history—Orson Welles with *Citizen Kane* and Huston's *The Maltese Falcon*, an elegantly perverse private-eye tale in which double-crosses occur at a bewildering rate, thereby setting the mould for the *film noir* that was so prominent later in the decade. Huston's career intermittently maintained this initial impetus, though public and critical reception of his works was not always judicious: *Freud: The Secret Passion* (1962), a remarkable drama ahead of its time, was ill received, whereas *The African Queen*, for which Bogart won an Oscar in 1952, is an overrated, though entertaining, film. Huston was intrigued by over-reachers, people who pursue their dreams to the point of obsession. Even when their obsessions blow up in their faces, as they do in two of his best films, *The Treasure of the Sierra Madre* (1948) and *The Man who would be King* (1975), Huston is still impressed by the grandeur of human aspiration, by the ironies of courage and cowardice, by the stirring way humanity challenges its fate. His work was uneven but his career ended on a high note: a typically literate adaptation of a literary classic, *Under the Volcano* (1984); an impish Mafia black comedy, *Prizzi's Honor* (1985); and a serene rendering of James Joyce's elegiac short story, *The Dead* (1987).His direction also helped win Oscars for his family: for father Walter in *Sierra Madre*, and for daughter Anjelica in *Prizzi's Honor*. Other films: *Key Largo* (1948), *Moby Dick* (1956), *The Misfits* (1961), *Reflections in a Golden Eye* (1967), *Fat City* (1972), *Wise Blood* (1979).

Kazan, Elia (1909–2003)

Dynamic director who founded the Actor's Studio with Lee Strasberg and is responsible for bringing the Method style of acting into the American cinema. His association on three films with Marlon Brando—*A Streetcar named Desire* (1951), *Viva*

Zapata (1952) and *On the Waterfront* (1954)—was significant for its establishment of the prototype Kazan hero: a rebel, anguished and ambivalent about his personal situation and social responsibilities but with a tremendous drive to solve his problems. *On the Waterfront* was particularly controversial for its so-called "glorification of the informer" (an ex-Communist, Kazan had named names to the House UnAmerican Activities Committee in 1952). He also directed James Dean in *East of Eden* (1955), Montgomery Clift in *Wild River* (1960) and Robert De Niro in *The Last Tycoon* (1976), though in his later years he occupied himself mainly in writing novels and a revelatory autobiography, *A Life*. Amid much controversy, he was awarded an honorary Oscar in 1999.

Kiarostami, Abbas (b.1940)

A leading figure of the new Iranian cinema. *Close-Up* (1989), an ironic and technically adroit story (based on fact) of a movie fanatic who impersonates a film director, first brought him to the attention of critics in the West. Since then, his films have been widely praised for their humanistic observation (often compared with that of directors such as Renoir, De Sica and Satyajit Ray) and their sympathetic insights into modern Iranian society. Key films include: *The Traveller* (1974), *Where is My Friend's House?* (1987), *Homework* (1989), *And Life Goes On* (1992), *A Taste of Cherry* (1997), *The Wind Will Carry Us* (1999), *Ten* (2002).

Kieslowski, Krzysztof (1941–96)

The greatest Polish directors, like Andrzej Wajda and Krzysztof Zanussi, see cinema as the nation's social conscience, the art-form that most courageously interrogates the country's moral and political values. Kieslowski was in that tradition and is best known abroad for his contemporary TV films on the theme of the Ten Commandments, two of which were expanded to feature-film length: *A Short Film About Killing* (1988) and *A Short Film About Love* (1989); and for his *Three Colours* trilogy, *Blue* (1993), *White* (1993) and *Red* (1994), which for some critics represents the finest achievement of European cinema in the 1990s. Other key films include: *Camera Buff* (1979), *No End* (1984), *The Double Life of Veronique* (1991).

Kubrick, Stanley (1928–99)

For Kubrick, the cinema was a laboratory for observation and experiment and his findings provoked more critical debate than any American director since Orson Welles. Two films in the 1960s particularly confirmed his extraordinary gifts: the nuclear comedy, *Dr. Strangelove* (1964), which showed the tension between man and the machine; and his sci-fi epic, *2001: A Space Odyssey* (1968), a vast enigmatic meditation on evolution and the degree to which man has been mastered by the technology he has created. His following two films, *A Clockwork Orange* (1971) and *Barry Lyndon* (1975) were amongst the most controversial of the next decade, the former for its violence in depicting the issue of free-will, the latter for its sumptuousness in anatomising high society at the end of the eighteenth-century. Some were disappointed with his labyrinthine horror film, *The Shining* (1980) and his Vietnam movie *Full Metal Jacket* (1987), but until his death he remained a key figure in modern film, analysing the tensions between the individual and history, man and science, language and social conditioning with a disturbingly clinical detachment. Other key films: *Paths of Glory* (1957), *Lolita* (1962) and *Eyes Wide Shut* (1999).

Kurosawa, Akira (1910–98)

Kurosawa was the first Japanese director to make a major impact on Western audiences with *Rashomon*, the recounting of a rape and murder from four separate perspectives, which was the great success of the Venice Film Festival in 1951. Compared to such as Mizoguchi and Ozu his work looks Westernised, but this can be of positive benefit, as in the Samurai "Westerns" he made with the actor Toshiro Mifune, where classic Western plot-schemes are translated into stylised Japanese settings (*The Seven Samurai*, 1954; *Sanjuro*, 1962). He also made highly praised adaptations of Shakespeare, *Throne of Blood* (1957), a version of *Macbeth*, and *Ran* (1985), an interpretation of *King Lear*. Psychological extremes always excited Kurosawa, and his pulsating visual style can be understood in terms of finding a powerful visual pattern to reflect the feverish inner intensity of his characters. But one should not overlook the strong humanist vein in Kurosawa, expressed most movingly in *Living* (1952). Other key films: *Drunken Angel* (1948), *The Idiot* (1951), *I Live in Fear* (1955), *The Lower Depths* (1957) and *Kagemusha* (1980).

Lang, Fritz (1890–1976)

Lang began as a leading exponent of German Expressionism, with the psychodrama *M* (1931), starring Peter Lorre as the self-hating child murderer, and *Metropolis* (1926), a science-fiction evocation of a nightmarish industrial city of the future. Goebbels was very taken with the latter film, and offered Lang the job of film-propaganda director to the Third Reich. Instead, he fled to America, and proceeded to provide auteurist critics with one of their juiciest test-cases by adapting his preoccupations with fate, revenge, and the social outcast to the turbulent American society of the pre-war and wartime years (*Fury*, 1936), and to genres such as the Western (*Rancho Notorious* in 1952) and the gangster film (*The Big Heat* in 1953).

Two Edward G. Robinson performances—as a Professor implicated in murder in *The Woman in the Window* (1944) and as an artist infatuated with a prostitute in *Scarlet Street* (1945)—embody to perfection the typical Lang hero, trapped by personality, circumstance and environment.

He is still arguably the most formidable pessimist in film history, and his presentation of fear and alienation in the modern metropolis profoundly influenced Godard, Hitchcock, Kubrick *etc*.

Lean, Sir David (1908–91)

The popular cinema's master story-teller. In *Brief Encounter* (1945), he made the British cinema's greatest love story; his Dickens' adaptations, *Great Expectations* (1946) and *Oliver Twist* (1948) have never been surpassed; and with *The Bridge on the River Kwai* (1957), *Lawrence of Arabia* (1962) and *Doctor Zhivago* (1965), he managed to align epic perspectives with intimate and intense characterisation. After the failure of *Ryan's Daughter* in 1970, his reputation slumped: "bourgeois impersonality" was the label given to his films. But the success of *A Passage to India* (1984) helped to force a re-evaluation of his work and recognise its individual qualities: the emotional repression of his heroines; the visionary madness of his heroes; the spirit of place that pulses in his films; and his sensitivity to the erratic, exotic emotions that lurk beneath the surface of English propriety. Other key films include: *The Sound Barrier* (1952), *Hobson's Choice* (1954) and *Summer Madness* (1955).

Lee, Ang (b.1954)

Emigrating from his native Taiwan to America in 1978 and learning his film craft at New York's University Film School, Ang Lee has amassed the most varied body of work of any director of the last decade. It ranges from domestic drama to a western; from martial arts to Jane Austen; from low-key comedy of observation, like the delightful *Pushing Hands* (1992), to high-tech comic-strip fantasy such as *Hulk* (2003) ; and from the visual splendour of *Crouching Tiger, Hidden Dragon* (2000) to the psychological depth of *The Ice Storm* (1997) and *Brokeback Mountain* (2005). Other key films: *The Wedding Banquet* (1993), *Eat Drink Man Woman* (1994), *Sense and Sensibility* (1995), *Ride with the Devil* (1999), *Lust, Caution* (2007), *Taking Woodstock* (2009) and *Life of Pi* (2012).

Leigh, Mike (b. 1943)

English director of international reputation after his success with *Secrets and Lies* (1996), a tragi-comic study of family relationships that is Leigh's forte. He had made his first film as far back as 1971, but only in the last two decades has he really developed some cinematic continuity. Cineastes cherish his quirky insight into character and his sharp, astringent, satire of middle-class mores. Key films: *Bleak Moments* (1971), *High Hopes* (1988), *Life is Sweet*

(1990), *Naked* (1993), *Career Girls* (1997), *Topsy Turvy* (1999), *All or Nothing* (2002), *Vera Drake* (2004), *Happy Go Lucky* (2008) and *Another Year* (2010).

Leone, Sergio (1921–89)

Leone will always be remembered as the director who re-invigorated the western genre in the 1960s and made a star of Clint Eastwood. His spaghetti westerns—*A Fistful of Dollars* (1964), *For a Few Dollars More* (1965), *The Good, the Bad and the Ugly* (1966)—were an iconoclastic blend of parody and anti-heroism that appealed to a distrustful, anarchic age. His later films, *Once Upon a Time in the West* (1968) and *Once Upon a Time in America* (1984) were operatic meditations on the western and the gangster film respectively.

Loach, Ken (b. 1936)

Untamed radical film-maker who cut his teeth on social realist TV dramas, notably the massively influential *Cathy Come Home*, and then brought the same intensity to his feature films, most memorably in *Kes* (1969), a work much admired for its social critique and documentary-style technique by directors such as Kieslowski. Like Mike Leigh, Loach experienced a new lease of life in the 1990s, twice winning the European Film of the Year Award—for *Riff-Raff* (1990) and *Land and Freedom* (1995)—without compromising his vision, integrity or socialism. His film, *The Wind that Shakes the Barley* (2006) won the Golden Palm at Cannes. In 2016 he won a second Golden Palm for *I, Daniel Blake*.

Losey, Joseph (1909–84)

There were several Joseph Loseys: the American Losey renowned for cogent moral fables such as *The Prowler* (1951) before the McCarthyist blacklist forced him out of America; the British Losey in which, with collaborators like actors Stanley Baker and Dirk Bogarde and writer Harold Pinter, he analysed the sexual mores and class corruption of English society, as in *The Servant* (1963), *Accident* (1967) and *The Go-Between* (1971); and the European Losey of the final phase of his career, when he adapted classics such as *A Doll's House* (1973) or Mozart's *Don Giovanni* (1980) or offered trenchant insights into recent political history, as in *The Assassination of Trotsky* (1972) and *Mr. Klein* (1976). With a style often verging on the baroque, Losey tackled a variety of subject matter, but the themes were consistent: the hypocrisy and deceit of dominant social and sexual attitudes. He had one of the most lucid intellects in movies. Other key films include: *The Boy with Green Hair* (1948), *Blind Date* (1959), *The Criminal* (1960), *King and Country* (1964) and *Secret Ceremony* (1968).

Lubitsch, Ernst (1892–1947)

The master of sophisticated sex comedy who, in Billy Wilder's phrase, "could do more with a closed door than most modern directors can do with an entire bedroom". Born in Berlin, Lubitsch brought a European flavour to Hollywood farce, satirising the pretension and insensitivity that sometimes go with wealth and position. His best remembered films are *Ninotchka* (1939), in which Garbo laughs, and *To Be or Not to Be* (1942), in which Jack Benny plays Hamlet. They are not only comedies: they are fervent anti-Nazi satires made at a time when Lubitsch must have known that the Europe of his youth, so lovingly evoked on screen, was being destroyed forever. Other key films: *Trouble in Paradise* (1932) and *The Shop Around the Corner* (1940).

Lumet, Sidney (1924–2011)

The most enduring of the generation of directors (including John Frankenheimer, Martin Ritt and Franklin Schaffner) who graduated to the cinema in the 1950s after learning their craft on television. Lumet's first film, the jury-room drama, *12 Angry Men* (1957) was an instant classic, and his best films have often returned to the themes of justice, law and order, civic corruption and abuse of police power. A child actor on stage, he has developed a powerful rapport with actors and some of his films rival Kazan's in the skill and intensity of the performances. Arguably over-prolific, undeniably humourless, Lumet has nevertheless amassed a powerful body of work that testifies to his talent, professionalism and liberal values. Key films include: *Long Day's Journey into Night* (1962), *Fail Safe* (1964), *The Hill* (1965), *Dog Day Afternoon* (1975), *Network* (1976), *Prince of the City* (1981), *The Verdict* (1982), *Running on Empty* (1987) and *Before the Devil Knows You're Dead* (2007).

Lynch, David (b. 1946)

One of the modern cinema's most unnerving directors. He achieved instant notoriety with the gruesome *Eraserhead* (1976); had a deserved success with the compassionate *The Elephant Man* (1980); but has since polarised critical opinion with such films as *Wild at Heart* (1990) and *Lost Highway* (1997), psychologically challenging or pretentiously incoherent, according to taste. His most fully achieved works to date are *Blue Velvet* (1987), a nightmarish investigation of the dark sexual secrets of 'typical' small-town America; and *Mulholland Drive* (2001), a mysterious mesmerising look at the American Dream.

Mackendrick, Alexander (1912–93)

The most consistently brilliant of the Ealing directors, making four of its most successful and enduring comedies: *Whisky Galore* (1949), *The Man in the White Suit* (1951), *The Maggie* (1954) and *The Lady-Killers* (1955). His American debut—an exposé of yellow journalism—*Sweet Smell of Success* (1957) was also remarkable, but after a series of abortive projects in the 1960s, Mackendrick retired from directing to become Dean of the film department of the California Institute of the Arts. He left behind a fine body of work, notable for its extraordinary insights into the world of children, its fascination with the dangers of innocence, and its mordant observation of the intricate yet inevitable ways in which humans fail to communicate. Other key films: *Mandy* (1952), *Sammy Going South* (1963) and *A High Wind in Jamaica* (1965).

Malle, Louis (1932–95)

Formerly an assistant to Robert Bresson and Jacques Cousteau, Louis Malle developed into one of the most esteemed of international directors. He made films as dashing as *Zazie dans le Metro* (1960), as disturbing as *Lacombe Lucien* (1973), as atmospheric as *Atlantic City* (1980), and as moving as *Au Revoir les Enfants* (1987). Malle often challenged the norms of society and the boundaries of cinema, exploring such risky subjects as eroticism (in *Les Amants* in 1958), incest (in *Murmur of the Heart* in 1971) and child prostitution (in *Pretty Baby* in 1979) and yet still achieving popular success and critical acclaim. Isolation and social alienation were recurrent themes, fittingly so perhaps for one of the least predictable and most individualistic film-makers of modern times. Other key films include: *Lift to the Scaffold* (1957), *Le Feu Follet* (1963), *My Dinner With Andre* (1982) and *Damage* (1992).

Mankiewicz, Joseph L. (1909–93)

To those who find Mankiewicz's films too wordy, he replied: "There can never be an excess of *good* talk". Mankiewicz was one of the most eloquent of Hollywood's writer directors, who began by writing dialogue for W. C. Fields and, he claims, Rin-Rin-Tin (an unused screen-play about a dog that hates its master, a familiar Mankiewicz theme). His greatest period was during the ten years after the War, in which he won the writing and directing Oscars for two consecutive years (for *A Letter to Three Wives* in 1949 and *All About Eve* in 1950) and also made Hollywood's best Shakespearian film (*Julius Caesar* in 1952). His career never really picked up momentum after his labours on the mammothly expensive *Cleopatra* (1963), though he was proud to claim that his last film *Sleuth* (1972) is the only film ever to have its entire cast—*i.e.* Laurence Olivier and Michael Caine—nominated for Oscars. There are a lot of interesting recurrent motifs in Mankiewicz—generation conflict, ghosts from the past that will not stay dead—and nobody has made more haunting use of the flashback. Other key films: *The Ghost and Mrs. Muir* (1947), *Five Fingers* (1952), *The Barefoot Contessa* (1954) and *Suddenly Last Summer* (1959).

Mann, Anthony (1909–67)

Anthony Mann is best remembered for a series of Westerns he made with actor James Stewart, which were striking for their dramatic use of landscape and the psychological instability of their heroes. In *Winchester 73* (1950), *Bend of the River* (1952), *The Naked Spur* (1953), and *The Far Country* (1955), Stewart plays an ostensibly noble but actually neurotic hero who, whilst undertaking a perilous journey across a treacherous landscape, must also root out the evil in himself. Mann also made fine thrillers, a classic epic (*El Cid* in 1961) and even a stylish musical (*The Glenn Miller Story* in 1954) but it was the Mann of the Western that really showed his quality as a director. Other key films: *The Man from Laramie* (1955), *Man of the West* (1958) and *The Fall of the Roman Empire* (1964).

Melville, Jean-Pierre (1917–73)

Melville was something of a father figure of the *Nouvelle Vague* because of his economical and independent production methods. He made an exemplary adaptation of Jean Cocteau's novel *Les Enfants Terribles* (1950). However, he is most celebrated for a series of poetic, stylised existential gangster films, among them *Second Breath* (1966), *The Samurai* (1967), and *The Red Circle* (1970), which particularly took their inspiration from Melville's favourite director, John Huston. (Melville had chosen his pseudonym after his favourite author, Herman Melville: his actual surname was Grumbach). Perhaps his masterpiece, though, and certainly his most personal film, is *Army of the Shadows* (1969), a film about the French Resistance that drew on his own personal experience in the war.

Minnelli, Vincente (1910–86)

The name Vincente Minnelli is synonymous with the MGM musical—*Meet Me in St. Louis* (1944), *An American in Paris* (1951), *The Band Wagon* (1953), *Gigi* (1958) and others. Yet he was also adept at comedy, and did some remarkably intense melodramas, of which *Lust for Life* (1955), his bio-pic of Van Gogh, and *The Bad and the Beautiful* (1952), his glittering dissection of Hollywood ruthlessness, are particularly notable. He was interested in the plight of the artist in society, and the superiority of the world of imagination to that of reality. Hollywood's Dream Factory proved a most congenial environment for this most elegant of stylists. Other key films: *The Pirate* (1948), *Madame Bovary* (1949), *Father of the Bride* (1950). *Brigadoon* (1953), *The Cobweb* (1955) and *Some Came Running* (1958).

Mizoguchi, Kenji (1898–1956)

For many, Mizoguchi is the greatest of all Japanese directors, but his films are still not that well known in the West. The most famous is *Ugetsu Monogatari* (1953), a ravishingly beautiful tale of ghosts and greed. Its articulation of history and fantasy, its lyrical style and its commitment to the treatment of women as equals are characteristic of the director. Other masterpieces include: *The Story of the Last Chrysanthemums* (1939), *The Life of Oharu* (1952), *Sansho the Bailiff* (1954).

Murnau, F. W. (1889–1931)

Murnau is renowned for three classics of silent film: *Nosferatu* (1922), the cinema's first version of the *Dracula* story and still the most frightening; *The Last Laugh* (1924), credited as being one of the few silent films to dispense with titles and remarkable for its fluid camera movement; and *Sunrise* (1927), his first American film. Tragically he was killed in a car crash in 1931.

Olmi, Ermanno (b. 1931)

An Italian director whose work is characterised by a sympathy for the working man and by a concern for human dignity. In films such as *Il Posto* (1961) and *The Tree of Wooden Clogs* (1979), he kept the spirit of neo-realism alive.

Ophuls, Max (1902–57)

For a long time regarded as a talented minor director of exquisite trifles, Ophuls has been reinstated by modern criticism to his rightful place as one of the greatest of forties and fifties directors. *Lola Montes* (1955) was his last film, about the beautiful "adventuress" who allows herself to be put on display in a circus ring at the end of her career. The swooping camera-movements and awareness of how feminine sexuality necessarily connotes being an object to be looked at are in evidence too in *Madame de . . .* (1953), as well as in the films he made in Austria, Germany and France before setting out to pursue his career in Hollywood. His best American film was the beautiful tragic romance, *Letter from an Unknown Woman* (1948); whilst both *Caught* (1949) and *The Reckless Moment* (1949) took conventional women's magazine material and, through intense visual style, transformed them into tense and subversive comments on romantic obsession and domestic imprisonment.

Oshima, Nagisa (b. 1932)

His name became familiar to most filmgoers only with *Ai No Corrida* (otherwise *Empire of the Senses*) in 1975. An innkeeper and his ex-servant make untiring love until she, at his behest, strangles him in the moment of orgasm. The much-touted erotic frankness–certainly far less surrogate than that in *Last Tango in Paris*—assumes its importance only when seen in conjunction with the film's critique of the situation of women in Japanese society. In his first international film, *Merry Christmas, Mr. Lawrence* (1983), he explored the strange bond which grows between a Japanese captain and a British prisoner of war: a variation of his typical themes of forbidden passion, and his preoccupation with society's "enemies" whose psychology he seeks to understand. He completed a documentary for the BBC, *Kyoto, My Mother's Place* (1991), which gives a fascinating account of his background. Other key films: *Diary of A Shinjuku Thief* (1968), *Boy* (1969), *The Ceremony* (1971) and *Empire of Passion* (1978).

Ozu, Yasujiro (1903–63)

Like Mizoguchi, Ozu is a director long known to the Western public through only one work—*Tokyo Story* of 1953, about a visit paid by an elderly couple to their children in the capital. Ozu's style is slow, his narrative-lines not exactly eventful, his photography from a low level (the seated position traditional for social intercourse in Japan) perhaps difficult for Westerners to adjust to. But now he is accepted as one of the most important innovators in film language, for the way in which his small-scale stories distil much that is important in Japanese life and history, and for the separating out of individual actions and gestures so that spectators have time fully to appreciate their implications. Key films include: *I Was Born But . . .* (1932), *There was a Father* (1942), *Late Spring* (1949), *Early Summer* (1951), *Good Morning* (1959) and *An Autumn Afternoon* (1962).

Pasolini, Pier Paolo (1922–76)

Pasolini's notorious death—murdered by a homosexual pick-up—could almost have been engineered as a publicity stunt to launch his final film, *Salo or the 120 Days of Sodom* (1976), in which the combination of intense and complex visual lucidity with a recoiling from the tyrannies of the twentieth century already evident in *Pigsty* (1969) reaches its zenith. Ideological revulsion from the present and an interest in the possibilities of film language motivate Pasolini's curious "Marxist-Freudian-Catholic" rewritings of classics for the screen—*Medea* (1969) and *The Decameron* (1971). His complex artistry is seen at its best in his first film, *Accatone!* (1961) and *The Gospel According to St. Matthew* (1964), an austere rendering of the Biblical story far removed from the Hollywood epic, and movingly attempting to reconcile Pasolini's Marxist political outlook with his religious mysticism.

Peckinpah, Sam (1925–84)

Peckinpah was a Hollywood maverick, associated with scenes of graphic violence photographed in loving slow motion. In fact, he had something of the visual lyricism and raucous male humour of John Ford, though whereas Ford disclosed the poetry behind America's pioneering past, Peckinpah explored its passions and perversions as well. He will always be remembered for *The Wild Bunch* (1969), his radical, revisionist Western that majestically dragged the genre, kicking and screaming, into the 20th century. Other key films: *Guns in the Afternoon* (1962), *Major Dundee* (1965), *Straw Dogs* (1971), *Pat Garrett and Billy the Kid* (1973) and *Cross of Iron* (1977).

Penn, Arthur (**b. 1922**)

An abrasive stylist, notable for his subversive way with popular film genres, his investigation of the reality behind legendary figures, and his insertion of counter-culture attitudes into mainstream movie-making. Key films: *The Left-Handed Gun* (1958), *The Miracle Worker* (1962), *Bonnie and Clyde* (1967), *Alice's Restaurant* (1969) and *Night Moves* (1975).

Polanski, Roman (**b. 1933**)

From early Surrealist shorts, Polanski moved into feature-length dramas of sexual tension with *Knife in the Water* (1962) and *Repulsion* (shot in England in 1965). The reputation for kinkiness he thereby gained was tragically highlighted when his wife, the actress Sharon Tate, was butchered by crazed followers of Charles Manson in 1969. His major box- office success has been the private-eye drama *Chinatown* (1974), in which Polanski himself slits open the nose of the character played by Jack Nicholson. He also breathed flesh and blood into the horror film with *Rosemary's Baby* (1968) and fresh life into the filmed literary classic with *Tess* (1979). His traumatic life has been recounted in his autobiography, *Roman*. His film, *The Pianist* (2002) was a major return to form and won him an unexpected Oscar as best director. Other key films: *Cul-de-Sac* (1966), *Macbeth* (1971), *The Tenant* (1976), *Oliver Twist* (2005), *The Ghost* (2010) and *Carnage* (2011).

Powell, Michael (**1905–90**) **and Pressburger, Emeric** (**1902–88**)

British cinema's most full-blooded fantasists, who peaked in the 1940s with such passionate and visually imaginative films as *The Life and Death of Colonel Blimp* (1943), *I Know Where I'm Going* (1945), *A Matter of Life and Death* (1946), *Black Narcissus* (1947) and their greatest success, *The Red Shoes* (1948). From the late 1950s, Powell went solo and created an enormous furore with *Peeping Tom* (1960), which was critically reviled at the time but has since attained classic status and is deeply admired by cineastes and fellow directors such as Martin Scorsese.

Preminger, Otto (**1906–86**)

Talented tyrant who thrived on controversy, whether it involved the use of "naughty" words in *The Moon is Blue* (1953) or the depiction of the world of the drug addict in *The Man with the Golden Arm* (1955). His best films are the detective thriller, *Laura* (1945), one of a number of Preminger's features about mysterious, irresistible women who lure men to their doom; and the courtroom drama *Anatomy of a Murder* (1959), a masterpiece of objectivity and ambiguity. Other films: *Angel Face* (1953), *Carmen Jones* (1954), *Bonjour Tristesse* (1957), *Advise and Consent* (1962), *The Cardinal* (1963).

Ray, Nicholas (**1911–78**)

Ray was one of the most inventive and consistent of Hollywood action directors, whose rhetorical question summed up his philosophy of cinema: "If it were all in the script, why make the film?" *Rebel Without A Cause* (1955) blazed the trail for a host of movies about rebellious youth, but the dignity of James Dean's performance and the symbolic richness of Ray's *mise-en-scene* have caused it to survive longer than most of its imitators. He enjoyed success also with Bogart, *In a Lonely Place* (1950) and Robert Mitchum, *The Lusty Men* (1952). The critics of *Cahiers du Cinema* particularly championed Ray's more extreme stylistic exercises, such as the feminist Western, *Johnny Guitar* (1954) and the baroque gangster film, *Party Girl* (1958). Alienated youth, the rebel, the outsider: these were the figures with whom Ray identified, sometimes melodramatically, often poetically. Other key films: *They Live By Night* (1948), *Knock on Any Door* (1949), *On Dangerous Ground* (1952), *Bigger Than Life* (1956) and *Bitter Victory* (1957).

Ray, Satyajit (**1921–92**)

Pather Panchali of 1955 introduced Indian cinema to a wider audience, and launched a highly successful trilogy, completed by *Aparajito* of 1957 and *The World of Apu* of 1959. The withdrawn, analytical style of Ray's output expanded with some of his work in the seventies (see *Company Limited*, 1972) to a greater awareness of the problems of Westernised India. His films were rooted in the tradition of the humanist documentary, influenced by the social concern of Italian neo-realists, and inspired by the natural lyricism of a director like Jean Renoir. Other key films: *The Music Room* (1958), *Charulata* (1964), *Days and Nights in the Forest* (1970), *The Middle Man* (1976), *The Chess Players* (1977) and *The Home and the World* (1984).

Reed, Sir Carol (**1906–76**)

Reed's reputation as one of the key directors of post-war British cinema rests on a small number of films: the Expressionist, *Odd Man Out* (1947), the last day-in-the-life of an IRA man on the run, and two adaptations of Graham Greene stories, *The Fallen Idol* (1948) and *The Third Man* (1949). Overall his films are notable for a self-effacing craftsmanship, a sympathy with the world of children, and a fascination with confrontations between innocence and experience. He won an Oscar for *Oliver!* (1968). Other key films include *Outcast of the Islands* (1951), one of the cinema's best adaptations of Conrad; and *The Man Between* (1953), using its post-war Berlin setting less evocatively than post-war Vienna in *The Third Man* but a gripping human drama nonetheless.

Renoir, Jean (**1899–1979**)

A career spanning nearly fifty years included one of the first great dramas to be shot entirely on location, *Toni*, made with a largely non-professional cast in the South of France in 1935; two magnificent performances from Michel Simon, in *La Chienne* (1931) and *Boudu Sauve Des Eaux* (1932); a period funded by the Left-wing Popular Front that produced the film about a workers' cooperative, *Le Crime de Monsieur Lange* (1935); and a forties and fifties output as an exile in Hollywood of considerable merit, including *The Southerner* of 1945. These would be enough to mark Renoir out as a significant director even were it not for his two pre- Second-World-War masterpieces, *La Grande Illusion* (1937),a drama set in a POW camp, and the matchless *La Regle du Jeu* of 1939. This savage and frequently hilarious drama of love, class-antagonism, and the ambiguous corruption of aristocratic style so quickly achieved recognition as a masterpiece that it requires an effort now to remind ourselves that it was banned on first release.

Resnais, Alain (**1922-2014**)

Resnais began as a documentarist, and made his first feature film in 1959—*Hiroshima Mon Amour*, from a screenplay by the novelist Marguerite Duras. *Hiroshima*'s concern with the interaction of time, place and memory was taken up and amplified in *Last Year in Marienbad* (1961), where there is no reassuring continuity of character or coherence of time or space other than that imposed ambiguously, from moment to moment by the "eternal present" of the screen. Speculation about *Marienbad* reached quasi-metaphysical heights that frequently tended to obscure the dazzling frozen eroticism of its *mise-en-scene*, its masterful exploitation of the dreamlike aspect of film-watching, and the performances of Georgio Albertazzi and Delphine Seyrig. Memory and imagination continued to be important preoccupations in his work, and he long remained one of the great "modernist" innovators of contemporary cinema, continually exploring new areas of expression. Key films: *Night and Fog* (1956), *Muriel* (1963), *Providence* (1977), *L'Amour à Mort* (1984), *Private Fears in Public Places* (2006), *Wild Grass* (2009).

Rosi, Francesco (b. 1922)

Rosi began as an assistant to Luchino Visconti and is perhaps best known as the maker of the Placido Domingo film of *Carmen* (1984). But his natural home is the world of political corruption and paranoia, and no modern film-maker can match him for his trenchant critique of the institutions of power. His key films in this vein are *Salvatore Giuliano* (1961), *Hands Over the City* (1963), *The Mattei Affair* (1972). *Illustrious Corpses* (1976), *Christ Stopped at Eboli* (1979) and *Three Brothers* (1981).

Rosselini, Roberto (1906–77)

A key figure in the Italian neo-realist movement, whose early films were made on shoestring budgets and in often difficult conditions (*e.g. Rome, Open City*, 1945, about the anti-Fascist Resistance, shot when Mussolini's troops were still occupying Rome). *Voyage in Italy* (1953), in its open-endedness and preoccupation with George Sanders' and Ingrid Bergman's fluctuating senses of cultural alienation, foreshadowed the psychological explorations of Antonioni. Other key films: *Germany Year Zero* (1948), *Stromboli* (1949) and *The Rise of Louis XIV* (1966).

Rossen, Robert (1908–66)

One of the most socially aware of Hollywood directors who made his mark in the late 1940s with a hard-hitting boxing saga *Body and Soul* (1947), which was actually an allegory of capitalist corruption, and the Oscar-winning *All the King's Men* (1949), an indictment of creeping political Fascism. But then, hounded by the House UnAmerican Activities Committee for his Communist affiliations, he finally recanted and named names. He was able to work again but became, according to friends, a haunted, withdrawn individual. But his last two films were remarkable returns to form: a study of character and courage around the pool table, *The Hustler* (1961), and a study of madness, *Lilith* (1964), which was condemned on its first release but has gained an underground reputation as one of the most lyrical films of the American cinema.

Sautet, Claude (1924–2000)

Highly regarded French director who began as a screenwriter and who belatedly secured recognition as a subtle anatomist of human behaviour through the international success of *Un Coeur en Hiver—A Heart in Winter* (1993) and *Nelly and M. Arnaud* (1995). Other key films: *Les Choses de la Vie—The Things of Life* (1970), *Cesar et Rosalie* (1972), *Une Histoire Simple—A Simple Story* (1978).

Scorsese, Martin (b. 1942)

Arguably the most exciting of modern American film-makers. His movies are notable for their restless camera movement which reflects the inner tension of the characters. He has collaborated particularly closely with actor Robert De Niro, forging the most important actor-director partnership in American film since Brando and Kazan in the 1950s. Together they have made emotionally lacerating films about troubled masculinity and with a religious sense of redemption. Sometimes criticised for misogyny, his films are among the most disturbing and challenging of mainstream cinema. Key films: *Mean Streets* (1973), *Taxi Driver* (1976), *Raging Bull* (1980), *The King of Comedy* (1983), *Goodfellas* (1990) *Cape Fear* (1991), *The Age of Innocence* (1993), *Casino* (1995), *Kundun* (1997), *Bringing Out the Dead* (1999), *The Gangs of New York* (2002), *The Aviator* (2004), *The Departed* (2006) (which won him an Oscar for Best Director), *Shutter Island* (2010), *The Wolf of Wall Street* (2013) and *Silence* (2016), set in 17th century Japan.

Siegel, Don (1912–91)

Siegel learnt his craft as head of montage at Warners before gaining a reputation on low budget thrillers such as *Riot in Cell Block 11* (1954), *Baby Face Nelson* (1957) and *The Line Up* (1958), that combined sharp observation of the social outsider with a real flair for staging violent action. The sci-fi classic *Invasion of the Body Snatchers* (1956) and a brilliant re-make of *The Killers* (1964) cemented his cult status, and his career achieved a decisive upturn through his association on five films with Clint Eastwood, notably on *Dirty Harry* (1971), where they created arguably the most controversial anti-hero of postwar cinema. Other key films: *Hell is for Heroes* (1962), *Madigan* (1968), *The Beguiled* (1971), *The Shootist* (1976) and *Escape from Alcatraz* (1979).

Siodmak, Robert (1900–73)

Siodmak made his directing debut on the low budget German film, *Menschen am Sontag- People on Sunday* (1929), a work that has become famous for also launching the careers of directors Billy Wilder and Fred Zinnemann and cameraman Eugene Schufftan. Like them, Siodmak moved to Hollywood, and he did his best work during the 1940s, making a number of fatalistic, visually gloomy dramas that are acknowledged as classics of film noir or Grand Guignol suspense: *Phantom Lady* (1944), *The Spiral Staircase* (1945), *The Killers* (1946), *Cry of the City* (1948), *Criss Cross* (1949).

Sirk, Douglas (1900–87)

Long regarded as a curiosity, Sirk was a Danish expatriate whose melodramas, richly shot and distinguished by narrative flamboyance, were at first treated with mild condescension. *Written on the Wind* (1956) was among the first to gain serious acceptance, with its dramatisation of the conflicts within a wealthy oil family whose problems (alcoholism, instability, sexual promiscuity) were sympathetically presented in a highly-coloured style.

His other works, notably *All That Heaven Allows* (1955) and *Imitation of Life* (1959), also began to receive more serious and sympathetic treatment as ironic and subversive critiques of middle-class America: they had a profound influence on the work of Fassbinder and inspired the recent film, *Far from Heaven* (2002). Other key films: *There's Always Tomorrow* (1956), *Tarnished Angels* (1957) and *A Time to Love and A Time to Die* (1958).

Spielberg, Steven (b. 1947)

The most successful director in the history of cinema, notably for four films: *Jaws* (1975), *Close Encounters of the Third Kind* (1977), *E.T. the Extra-Terrestrial* (1982) and *Jurassic Park* (1993). His films are basically about ordinary people in extraordinary situations, and he directs these with a witty eye for the mores of American suburbia and a tremendous flair for suspense. A new maturity came into his work with *The Color Purple* (1985), *Empire of the Sun* (1987) and *Schindler's List* (1993), his unexpected powerful film of the holocaust. Often attacked for sentimentality, his work has been defended by the novelist J.G. Ballard, who has described Spielberg as the "Puccini of cinema – too sweet for some tastes, but what melodies, what orchestrations, what cathedrals of emotion ..." Other key films: *Duel* (1971), *The Sugarland Express* (1974), *Raiders of the Lost Ark* (1981), *Amistad* (1997), *Saving Private Ryan* (1998), *Minority Report* (2002), *The War of the Worlds* (2005), *War Horse* (2011) and *Lincoln* (2013). His *Bridge of Spies* and *Ready Player One* are his most recent works. Awarded Honorary Knighthood, 2001.

Stevens, George (1904–75)

Beginning as a camerman on Laurel and Hardy shorts, Stevens' early reputation as a director was in comedy: *Woman of the Year* (1942) and *The More the Merrier* (1943). But his war experience, which included being part of the American force that liberated Dachau, changed his sensibility: comedy receded and his films became full of a feeling of tragic sacrifice. *The Diary of Anne Frank* (1959) is his memorial to the war dead. His own movie monument is probably a trio of films that encapsulates his sympathy for the outsider and constitutes his epic reassessment of the American Dream: *A Place in the Sun* (1951), *Shane* (1953), and *Giant* (1956). Other key films: *Alice Adams* (1935), *Gunga Din* (1939), *Talk of the Town* (1942), *I Remember Mama* (1948) and *The Greatest Story Ever Told* (1965).

Stone, Oliver (b. 1946)

Vietnam vet turned polemicist director. He turned his Army experience into compelling cinema in *Platoon* (1986) and *Born on the Fourth of July*

(1989), for which he won directing Oscars, and his bio-pics of *JFK* (1991), *Nixon* (1995) and *George W. Bush, 'W'* (2008) were powerfully paranoid assaults on the American political system. Often derided for the extreme views and excessive violence of his films, Stone has been nonetheless a provocative influence. Other key films: *Salvador* (1985), *Wall Street* (1987), *Natural Born Killers* (1995).

Sturges, John (**1911–92**)

One of the finest directors of westerns. His masterpiece is *Bad Day at Black Rock* (1955), which is both modern western and suspense thriller, and his other contributions to the genre include: *Escape from Fort Bravo* (1954), *Gunfight at the O.K. Corral* (1957), *The Law and Jake Wade* (1958), *Last Train from Gun Hill* (1959), and *The Magnificent Seven* (1960). Also of note is the classic war film, *The Great Escape* (1963).

Sturges, Preston (**1898–1959**)

One of the first great writer-directors of the sound era in Hollywood, Sturges sold his screenplay *The Great McGinty* (1940) to Paramount for ten dollars on the condition he was allowed to direct. It was the first of eight comedies he wrote and directed within four years, each of which was interesting, some of which—*The Lady Eve* (1941), *Sullivan's Travels* (1942), *Palm Beach Story* (1942)—are classics. His comedies are distinguished by a frantic pace, tremendous ingenuity of dialogue and situation, and an air of shrill desperation. His characters comprise hapless millionaires, seductive gold-diggers and frustrated inventors, all whipped together in a sustained assault on American sacred cows.

Tarantino, Quentin (**b.1963**)

Former video store clerk and movie fanatic who became the most copied and discussed cult director of the 1990s. His first film, *Reservoir Dogs* (1991), about a heist that goes wrong, showed his gift for sharp dialogue and ingenious story-telling, but it was his second, *Pulp Fiction* (1994) that really caught the popular, post-modernist imagination. This underworld tale, with its outrageous violence, narrative surprises and subversively playful tone amidst the pervasive amorality, has since been much imitated but never equalled—not even, to date, by Tarantino himself. His *Inglourious Basterds* was released in 2009 and *Django Unchained* in 2013. His most recent film is *The Hateful Eight* (2015).

Tarkovsky, Andrey (**1932–86**)

The greatest Soviet film-maker since Eisenstein—and the resemblance ends there. Tarkovsky found his inspiration not in the spirit of the Russian Revolution but in the spirituality of the classic Russian novel, and the questions his films posed were not about the nature of political power but about the possibilities of personal salvation. This inevitably brought him into conflict with the Soviet authorities, who disliked the unsocialist, surreal, avant-garde qualities in films such as *Andrei Rublev* (1966) and *Mirror* (1974). They also took exception to Tarkovsky's thinly concealed allegory of the struggles of the artist in a repressive society. His last films were made in exile, and his final film, *The Sacrifice* (1985), a typically hallucinatory drama about a dream of nuclear holocaust averted, was one of his most movingly accessible and affirmative. A dreamer, a poet, a prophet, Tarkovsky's provocative and challenging thoughts on cinema were published in his book, *Sculpting in Time* (1987). Other key films: *Ivan's Childhood* (1962), *Solaris* (1971), *Stalker* (1979) and *Nostalgia* (1982).

Trier, Lars von (**b.1956**)

A signatory to the Dogme 95 manifesto which rejected cinema artifice and extravagance, von Trier has nevertheless made films of prodigious imagination and experimentation that have provoked extreme critical reaction, both for and against. Few would deny his claim to be the most important Danish film-maker since Carl Dreyer, although many would query his self-description as the world's greatest director. Key films: *The Element of Crime* (1984), *Europa* (1991), *The Kingdom* (1994), *Breaking the Waves* (1996), *The Idiots* (1998), *Dancer in the Dark* (2000), *Dogville* (2003) and *Antichrist* (2009).

Truffaut, Francois (**1932–84**)

With Godard, one of the outstanding early names of the so-called French "New Wave". Truffaut's early work reveals a delight in the possibilities of the cinematic medium (notably in evoking situations of emotional fluidity and ambiguity) that is often exhilarating, as in *Shoot the Pianist* (with Charles Aznavour, 1960) and his masterpiece, *Jules et Jim* (1961). This deals with a menage a trois in the France of the beginning of the century, portrayed with tragic irony and a light yet serious treatment of historical and cultural influences on the relationship between Catherine (Jeanne Moreau) and her two lovers, the German Jules and the Frenchman Jim. His first feature film, *The 400 Blows* (1959) drew on his own difficult childhood and delinquent adolescence, and later films like *L'Enfant Sauvage* (1970) also deal sensitively with the world of childhood. He also made films like *Fahrenheit 451* (1965) and *The Bride Wore Black* (1968) in homage to Hitchcock. In the 1970s he made two of his most haunting films on his favourite theme of romantic obsession, *The Story of Adele H* (1975), and *The Green Room* (1978), but he also made one of the most affectionate of all films about film-making, *Day for Night* (1973). Truffaut loved movies and his death left cineastes feeling that they had lost a member of the family.

Vertov, Dziga (**1896–1934**)

Often seen as the great documentary director, as Eisenstein was the great feature director, of the early Bolshevik Russian days. His principal work is *The Man with a Movie Camera* (1929), an exhilarating exploration of the relationship between the camera, the person holding it, and the subject-matter being filmed.

Vidor, King (**1894–1982**)

A pioneer of the cinema, responsible for two of the masterpieces of American silent film, the World War One drama, *The Big Parade* (1925), and the urban realist classic, *The Crowd* (1928). His films of the sound era were less distinguished, curiously at their most impressive when he foresook realism in favour of melodrama. Key films include: *Hallelujah* (1929), *Our Daily Bread* (1934), *Stella Dallas* (1937), *The Citadel* (1938), *Duel in the Sun* (1947), *Ruby Gentry* (1952), *War and Peace* (1956).

Vigo, Jean (**1905–34**)

A great Surrealist director, whose early death from tuberculosis meant that he produced only two feature films, both masterpieces: *Zero de Conduite* (1933), an account of a rebellion in a repressive boys' school whose fragmentary, night-marish quality (partly a result of the tight conditions under which it was shot) is exceptional, and *L'Atalante* (1934), about a honeymoon on a barge, a haunting blend of lyricism and realism.

Visconti, Luchino (**1906–77**)

The most emotive and extravagant of the Italian neo-realists. Visconti came to attention with *La Terra Trema* (1948), about Sicilian fishermen; a mixture of tragic fatalism and concern for social change characteristic of Visconti pervades this, as it does the operatic *Rocco and his Brothers* of 1960 and his adaptation of the novel by Lampedusa, *The Leopard* (1963). Aristocrat yet communist, arthouse director who loved working with stars (like Dirk Bogarde and Burt Lancaster), Visconti was a strange mixture of extremes. His films dealt with forbidden passions; tormented heroes imprisoned by the standards of a society they despise; and superficially cultured ways of life in their death- throes. Nobody recreated the past more sumptuously on the screen than Visconti nor photographed doom more voluptuously. Other key films: *Ossessione* (1942), *Senso* (1954), *The Damned* (1969), *Death in Venice* (1971), *Ludwig* (1972) and *Conversation Piece* (1974).

Von Sternberg, Josef (**1894–1969**)

The supreme exponent of cinema as icon, of the image whose lavish and elaborate composition is its most immediately apparent justification. Yet his films are astounding essays on the infinite varieties of love, in which the love object (invariably Marlene Dietrich) is alternately the exploited victim or the tyrannical temptress. He never created real worlds: his films are stylised sound stages of dream and desire. Key films: *The Blue Angel* (1930), *Morocco* (1930), *Shanghai Express* (1932), *The Scarlet Empress* (1934) and *The Devil is a Woman* (1935).

Von Stroheim, Erich (1885–1957)

"By God I told them the truth" said Stroheim of his classic film *Greed* (1923). Unfortunately for MGM, he told it at excessive length, and the film was cut from 42 to 10 reels in length. Stroheim's career as director never recovered from this. But John Grierson was to call him "the director of directors", for his unflinching realism and fanatical attention to detail. Billy Wilder thought he was ten years ahead of his time, though Stroheim contradicted him: "No—twenty". Key films: *Foolish Wives* (1922), *Merry-Go-Round* (1923) and *Queen Kelly* (1928).

Wajda, Andrzej (1926–2016)

Perhaps the most important film-maker Poland has ever produced. Wajda grew up in Poland during the Nazi occupation and his famous trilogy—*A Generation* (1955), *Kanal* (1956) and *Ashes and Diamonds* (1958)—records the wartime suffering and courage and the scramble for political power that followed the liberation. *Ashes and Diamonds*, in particular, with its charismatic performance by Zbigniew Cybulski, exemplified Wajda's fascination with heroes who refuse to follow the tide of history and attempt to shape their own destinies through extreme action. For a time, history took second place to psychology and symbolism in his work. But in the mid 1970s, he returned head-on to contemporary issues, tackling the theme of censorship, political blackmail and the film-maker's responsibilities in *Man of Marble* (1976), and celebrating the rise of Solidarity in *Man of Iron* (1980) in a tone of prophetically precarious optimism. Wajda's films were often set in transitional periods where one era has died and another is struggling to be born. His own career was also subject to the turbulent tides of history, facing censorship, exile and rejection, but his achievements stand as an inspiring example of artistic talent surviving against difficult odds. Other key films: *Innocent Sorcerers* (1961), *Everything for Sale* (1968), *The Wedding* (1973), *The Conductor* (1980), *Korczak* (1988) and *Katyn* (2007).

Welles, Orson (1915–85)

Welles made his debut with *Citizen Kane* in 1941; over seventy years later, it is still a popular choice as the best film ever. Innovatory in film language (in its bold and extensive use of "deep-focus"—the camera plunging into the imaginary "depth" of the screen), suggestive in its plot (about a tycoon, modelled on William Randolph Hearst, whose public success is seen as a remedy for private unhappiness), electric in the quality of its camerawork and ensemble acting, and with its finale (the "secret" of Kane's life—the name of his confiscated childhood sledge, Rosebud) the most ironically well-kept secret in cinema history, the film succeeded on so many levels that hindsight almost suggests that Welles's subsequent career had to be an anticlimax. He filmed Shakespeare (*Macbeth*, 1948, *Othello*, 1952, *Chimes at Midnight*, 1966), Kafka (*The Trial*, 1963) and a "documentary" about forgeries (*F. for Fake*, 1975), none to the effect of *Kane*. Nevertheless the qualities of his other films should not be overlooked: the tenderness of *The Magnificent Ambersons* (1942), the *film noir* virtuosity of *Lady from Shanghai* (1948), the magisterial study of police corruption in *Touch of Evil* (1958).

It is tempting to see *Kane* as a prophetic study of promise unfulfilled, and Welles's career certainly had more than its share of disappointments and frustrations. But he still remains a giant of the cinema, probing themes of power and corruption with that virtuoso camera style that he said "describes that sense of vertigo, uncertainty, lack of stability, that melange of movement and tension that is our universe".

Wenders, Wim (b. 1945)

One of the major figures of the "New German Cinema" of the 1970s, cooler and less didactic than Fassbinder, more streetwise and less anti-American than Herzog. His ambivalent response to America's "Coca-colonisation" of Europe was explored in *The American Friend* (1977), which had guest roles for Nicholas Ray and Samuel Fuller; and films such as *The Goalkeeper's Fear of the Penalty* (1972) and *Kings of the Road* (1976) elaborated his interest in the alienation of the modern environment and the rootlessness of modern man. His biggest international successes to date are *Paris Texas* (1984), a film as remarkable for its disorienting landscape as its characters or story; and *Wings of Desire* (1987) which won the top prize at the Cannes Film Festival.

Wilder, Billy (1906–2002)

"It's not important that a director knows how to write," said Billy Wilder, "but it is important that he knows how to read." Fleeing from Nazi Europe and becoming a Hollywood screenwriter for, among others, Ernst Lubitsch, Wilder became a director in order to protect his own scripts. *Double Indemnity* (1944), *The Lost Weekend* (1945) and *Sunset Boulevard* (1950) were wonderfully macabre demonstrations of his talents, and films like *Ace in the Hole* (1951), *Some Like it Hot* (1959) and *The Apartment* (1960) consolidated his reputation as the sharpest satirist in Hollywood, with an unusually mordant view of human nature that did not, however, preclude the possibility of redemption. *Sabrina* (1954) and *Avanti!* (1972) showed the melting of American materialism by European romanticism. His care for structure, his unceasing verbal wit and the intelligence of his character development made Wilder's overall achievement the equal of any Hollywood director's of the sound era. Other key films: *Stalag 17* (1953), *Witness for the Prosecution* (1957), *One, Two, Three* (1961), *The Fortune Cookie* (1966), *The Private Life of Sherlock Holmes* (1970) and *Fedora* (1978).

Wong, Kar-Wei (b.1958)

Major figure of Hong Kong cinema, a director who specialises in visually exquisite, emotionally delicate stories of unrequited, unconsummated or understated love. This is seen to particularly exhilarating effect in *Chungking Express* (1994), his most famous film to date and one of the best films of the 1990s. Other key films: *As Tears Go By* (1988), *Fallen Angels* (1995), *Happy Together* (1997), *In the Mood for Love* (2000) and *2046* (2004).

Wyler, William (1902–81)

One of the master craftsmen of Hollywood film. As well as winning three Oscars for himself (for *Mrs. Miniver*, 1942; *The Best Years of Our Lives*, 1946; and *Ben-Hur*, 1959), Wyler elicited more than a dozen Oscar-winning performances from his casts. Although he could handle the epic canvas as well as anyone, his forte was for drama in a confined setting and struggles for territorial advantage in a marriage or family. *The Little Foxes*, (1941), *The Heiress* (1949) and *Carrie* (1952) are all masterpieces of domestic claustrophobia. Whilst his heroes tended to be withdrawn figures, needing to be convinced of the necessity for action (like the pacifist hero of *The Big Country*, (1958)), his heroines are more often dynamic creatures, kicking against the constraints of a masculine world. No wonder he was Bette Davis's favourite director and directed her in some of her best films: *Jezebel* (1938), *The Letter* (1940) and *The Little Foxes*. Although recurrent patterns and themes are discernible in his films (unrequited love, class confrontations between the complacent and the envious), he tended, like Huston, to subordinate his personality to the requirements of the story. For this reason, he has often been underestimated by *auteurist* critics. But if a great director is simply someone who has made a number of great films, Wyler was a great director. Other key films: *Dodsworth* (1936), *Wuthering Heights* (1939), *Roman Holiday* (1952) and *The Children's Hour* (1961).

Yimou, Zhang (b. 1950)

One of the key figures of modern Chinese cinema, an actor and cameraman (on Chen Kaige's *Yellow Earth* and *The Big Parade*) before turning to direction. Behind the sumptuous visual surfaces of his films lurk some telling observations on politics and patriarchy that have sometimes antagonised the Chinese authorities. His films also made a major star of his then leading actress Gong Li, whose characterisations often and excitingly subvert the stereotype of female submissiveness. The epic adventures *Hero* (2003) and *House of Flying Daggers* (2004) both proved an unexpected crossover success. Key films: *Red Sorghum* (1988), *Ju Dou* (1990), *Raise the Red Lantern* (1991), *The Story of Qui Ju* (1992), *Shanghai Triad* (1995), *Not One Less* (2000) and *The Great Wall* (2017).

Zinnemann, Fred (1907–97)

Born in Vienna, Zinnemann came to America in 1929, but his career did not really take off until *The Search* in 1948, a story of European children orphaned by the war and which presaged a number of his films about the impact and aftermath of war.

But it was the western *High Noon* (1952) that established both Zinnemann's reputation and his fundamental theme: that of individual conscience. At considerable personal risk but on a point of principle, a character takes a stand against a community or institution that wishes him to compromise and conform: it is the theme also of *From Here to Eternity* (1953), *The Nun's Story* (1959) and *A Man for All Seasons* (1966). Unusually for Hollywood, these were dramas of reaction, not action, and with melancholy rather than happy endings. Their critical and commercial success testified to Zinnemann's skill at popularising complex themes without compromising his vision. Other key films: *The Seventh Cross* (1944), *Act of Violence* (1949), *Member of the Wedding* (1952), *Day of the Jackal* (1973) and *Julia* (1977).

3. FAMOUS SCREEN ACTORS AND ACTRESSES

Andrews, Dame Julie (b. 1935)

The archetype of screen virtue who reached her peak of popularity in the mid-1960s with *Mary Poppins* (1964) and *The Sound of Music* (1965), in both of which her "English rose" image and pure singing voice enchanted audiences. She later made a number of films for her second husband, director Blake Edwards, but without the same success.

Arbuckle, "Fatty" (1887–1933)

Superb silent comedian whose career was ruined when accused of the rape and murder of a starlet Virginia Rappe at a wild Hollywood party in 1921. Although completely cleared of all charges, Arbuckle was never allowed to appear on the screen again (the whole story is told in David Yallop's book, *The Day the Laughter Stopped*). Buster Keaton, who owed his start in movies to Arbuckle, said he learnt everything about film from him.

Astaire, Fred (1899–1987)

"Can't act, slightly bald, can dance a little", was the verdict of the screen test of Astaire, who, in partnership with Ginger Rogers, was to become the most stylish screen dancer in Hollywood history. He starred in such classic musicals as *Top Hat* (1935), *Swing Time* (1936), *Easter Parade* (1948) and *Funny Face* (1956). Turned to straight acting in his later career with such effect that Spencer Tracy felt threatened and sent the following wire to his friend: "You stop acting or I'll start dancing!"

Bacall, Lauren (1924–2014)

Bacall was one of the first examples of Hollywood's skill at playing on-and-off screen personas off against each other. Opposite Humphrey Bogart in *To Have and Have Not* (1944), she enchanted him on the screen as she did in real life while the film was being shot. (They were later to be married.) Her performance there is a remarkably knowing and ironic one (particularly in the famous scene where she tells Bogart how to whistle for her if he wants anything), and she was to play similar roles opposite him in *The Big Sleep* (1946), *Dark Passage* (Delmer Daves, 1947) and *Key Largo* (John Huston, 1948). Although she was never really able to repeat her success with Bogart, her persona in these films is interesting as a contrast to the submissive view of women often purveyed by Hollywood. She was a great survivor and was nominated for an Oscar for her role in Barbra Streisand's *A Mirror has Two Faces* (1996). The last of the Hollywood greats.

Bardot, Brigitte (b. 1934)

"Created" by her then-husband Roger Vadim in *And God Created Woman* (1956), Bardot epitomised a certain popular view of French female sexuality—poutingly sensual, sporting a St. Tropez suntan and little else besides, as ardent and capricious in her off-screen romances as in those for the cameras. In Julien Duvivier's *La Femme et le Pantin* (1958) and Vadim's *Warrior's Rest* (1962) she exploited this role to perfection; but she did show that she had some acting ability in *Le Mepris*, made for Jean-Luc Godard in 1963, in *Viva Maria* (1965) for Louis Malle, and in *La Verité* (1960) for Henri-Georges Clouzot. Retired from the screen to devote herself to ecological issues.

Beatty, Warren (b. 1937)

Many people think of Beatty's career as beginning with *Bonnie and Clyde* (Arthur Penn, 1967), in which his performance as the debonair yet sexually insecure bandit Clyde steals the show. But he sprang to prominence as early as 1961 (Elia Kazan's *Splendour in the Grass*), and has appeared infrequently, but always to great effect, ever since, his best post-Bonnie performance perhaps being the gambler McCabe in Altman's *McCabe and Mrs. Miller* (1971). Directorial ambitions then preoccupied him more than acting, and he won an Oscar for the direction of *Reds* (1981). He appeared as a controversially honest politician in *Bulworth* (1998)—a role he has sometimes threatened to play in real life.

Belmondo, Jean-Paul (b. 1933)

Belmondo sprang to fame with his performance as the confusedly amoral Michel Poiccard in Godard's *Breathless* (1959). This earned him recognition as one of the first "anti-heroes" of the European cinema, concerned with discovering himself through action and, in his second masterpiece for Godard, *Pierrot le Fou* (1965), contemplation as well. Both films featured Belmondo "betrayed", ostensibly by the women he chose (Jean Seberg and Anna Karina respectively), but as much by his own insecure openness. His later work (including *Borsalino* for Deray in 1970, and *Stavisky* for Resnais in 1974) tended to be glossier and more spectacular, to the detriment of the "anti-hero" persona, though he scored a big personal success in Claude Lelouch's updating of *Les Miserables* (1994).

Bergman, Ingrid (1915–82)

Enticed, like Greta Garbo, from Sweden to Hollywood at the end of the thirties, Bergman became one of Hollywood's star actresses, particularly in exotic "European" roles like that of Humphrey Bogart's lost *grand amour* in Michael Curtiz's *Casablanca* (1943) and in three films for Hitchcock, *Spellbound* (1945), *Notorious* (1946) and *Under Capricorn* (1949). She went on to freelance in Europe in the fifties, notably for Roberto Rosselini (whom she married), in neo-realist classics such as *Stromboli* (1950) and *Voyage in Italy* (1953). Made a triumphant comeback to Hollywood in *Anastasia* (1956), and in her later years had great success in *The Murder on the Orient Express* (1974), for which she won her third Oscar, and in Ingmar Bergman's *Autumn Sonata* (1978).

Binoche, Juliette (**b. 1964**)

Born in Paris, Juliette Binoche has become one of the star actresses of modern European cinema, whose screen aura of wounded sensuality has been deployed to powerful effect by major directors such as Louis Malle in *Damage* (1992), Krzysztof Kieslowski in *Three Colours: Blue* (1993) and Michael Haneke in *Code Unknown* (1999) and *Caché* (2005).

She enhanced her international profile with an Oscar-winning performance as the nurse in *The English Patient* (1996) and also scored a personal success in the popular romance, *Chocolat* (2000).

Bogarde, Sir Dirk (**1921–99**)

It takes an effort to remind ourselves that the Bogarde destroyed by his death-wish passion for a young boy in Visconti's *Death in Venice* (1971) began his acting career in British comedy and melodrama and acquired real prominence as the accident-prone medical student in the "Doctor" films of the late fifties. His fine performance as a homosexual barrister in *Victim* (1960) marked a turning point and Joseph Losey exploited his dramatic acting talent in *The Servant* (1963), which played off his British reserve against a highly-charged situation as Losey was also to do in *Accident* (1967). The association with Visconti confirmed him as one of the screen's subtlest and most accomplished actors.

Bogart, Humphrey (**1899–1957**)

One of the all-time superstars. Bogart began as a stage actor and graduated to screen stardom with one of his theatre roles, the psychopathic gangster in *The Petrified Forest* (1936). He became famous in the forties as an "outsider" figure, caught up in corrupt or devious situations from which he tried to stay aloof through a basic decency masquerading as hard-bitten cynicism. *Casablanca* (1943) revealed the persona to have a soft heart, in the scenes where he drinks to forget his love for Ingrid Bergman—or rather to remember it—and where he sacrifices it in the airport scene at the end with the immortal: "Here's looking at you, kid". For Howard Hawks he made *To Have and Have Not* in 1944 and *The Big Sleep* in 1946, both with Lauren Bacall and both exploiting the same persona. Small wonder that fifties anti-hero Belmondo elevated him to a god in *Breathless* (Godard, 1959), as did Woody Allen in a different way in *Play it Again, Sam* (1972). Closely associated with director John Huston, for whom he made six films, including *The Maltese Falcon* (1941), *The Treasure of the Sierra Madre* (1948) and the film which won his Oscar, *The African Queen* (1951).

Bow, Clara (**1905–65**)

Known as the "It" girl because of her enormously popular personal success in the film *It* (1927). Epitomised the "Roaring 20s" during the silent era but her career then foundered because of sound, scandals and mental illness. She was the Monroe of her time: a sad fate.

Brando, Marlon (**1924–2004**)

Brando came to the cinema from the stage, a leading proponent of the "Method" school of acting which relied upon naturalistic empathy with the part rather than careful professional stylisation. Laconic violence, often tending to the inarticulate, was his early stock-in-trade, exemplified in *A Streetcar Named Desire* (1951) and *On The Waterfront* (1954), both directed by Elia Kazan. Other rebels vied with Brando in the late fifties and sixties, and his career went into an eclipse from which it was rescued by two very different, but remarkable, performances as men aware that they have passed their personal peak—the *Mafioso* Don Corleone in Coppola's *The Godfather* (1972), and the self-loathing American in Bertolucci's *Last Tango in Paris* (1973). He later tended to confine himself to expensive guest performances in movies like *Superman* (1980), though he gave a superb character performance as a Scottish liberal lawyer in the anti-apartheid drama, *A Dry White Season* (1989). Published a much publicised autobiography in 1994.

Brooks, Louise (**1906–85**)

Magnetic star whose film fame rests mainly on one charismatic performance: as Lulu in G. W. Pabst's *Pandora's Box* (1929). She retired from the screen in the early 1930s and led a reclusive life, though briefly surfaced to write a marvellous book of memoirs, *Lulu in Hollywood.*

Burton, Richard (**1925–84**)

Burton was initially a leading stage Shakespearian, but better-known to the cinema public for his flamboyant romance with Elizabeth Taylor. His performance as the verbally aggressive college professor in Mike Nichols's *Who's Afraid of Virginia Woolf ?* (1966) marked him out as a great screen actor, as did his performance in *The Spy who came in from the Cold* (1965).

He was nominated seven times for the coveted Oscar without winning: his last performance was as the sinister interrogator O'Brien in the 1984 screen adaptation of George Orwell's *1984*.

Cagney, James (**1899–1986**)

Pugnacious leading man who started out as a dancer but whose energy and vitality made him ideal for the dynamic gangster movies of the 1930s, such as *Public Enemy* (1931), *Angels with Dirty Faces* (1938) and *The Roaring Twenties* (1939). Won an Oscar for *Yankee Doodle Dandy* (1942) but his most memorable characterisation was probably as the psychopathic, mother-fixated Cody Jarrett in Raoul Walsh's *White Heat* (1949).

Caine, Sir Michael (**b. 1933**)

Durable, dependable British star who, rather like Robert Mitchum, conceals his range and professionalism beneath a deceptively languid style. Came to the fore in the 1960s, particularly for his performance in the title role of *Alfie* (1966): thereafter he has remained in demand through a skilful balance of the commercial with the more challenging. Won supporting actor Oscars for *Hannah and Her Sisters* (1986) and *The Cider House Rules* (1999).

Other films include *Zulu* (1964), *Get Carter* (1971), *The Man Who Would be King* (1975), *Educating Rita* (1983), *Little Voice* (1998), *The Quiet American* (2002) and *Harry Brown* (2009).

Chaplin, Sir Charles (**1889–1977**)

Still the most famous film star and director in the history of movies. His creation of the "little man"—the wistful tramp figure who fantasises his way out of the hardships of life—achieved success on an unprecedented scale and effectively made the transition from silent shorts to feature-length films, the most famous being *The Gold Rush* (1925). He fought hard against the coming of sound, refusing to use any apart from music and sound effects in *City Lights* (1931), where the blend of slapstick and suspense was particularly well achieved. His later films, like *Modern Times* (1936), *The Great Dictator* (1940) and *Monsieur Verdoux* (1947) were infused with his socialist political sympathies which set him at odds with the American authorities and led to his exile in 1952.

He remains the most significant and creative film comic of the twentieth century.

Christie, Julie (**b. 1941**)

Beautiful British actress who shot to international stardom with her performance in *Darling* (1965) and *Doctor Zhivago* (1965). Her best films include *Petulia* (1968), *The Go-Between* (1971), *McCabe and Mrs. Miller* (1971) and *Don't Look Now* (1973). In recent years, she has developed into a character actress of stature, particularly with her performances in *Hamlet* (1997), *Afterglow* (1997) and *Away from Her* (2007).

Clift, Montgomery (**1920–66**)

Clift now enjoys a vogue as one of the great Hollywood victims, destroyed by drink, pills and inability to come to terms with his homosexuality. This litany should not obscure the fact that he was a tremendously gifted screen actor, as a tormented priest in *I Confess* (Hitchcock, 1952), as a cowboy opposite John Wayne in Hawk's *Red River* (1948), or with Clark Gable and Marilyn Monroe in that most macabre of pictures (it marked the end of virtually all its stars' careers), John Huston's *The Misfits* of 1961. Other key performances include *A Place in the Sun* (Stevens, 1951), *From Here to Eternity* (Zinnemann, 1953) and *Freud* (Huston, 1962). Speaking of his tormented personality, Marilyn Monroe once commented: "He's the only person I know who's in worse shape than I am."

Connery, Sir Sean (**b. 1930**)

Connery achieved early fame as the first of the screen James Bonds, but has been recognised as one of the best character-actor stars of modern cinema. Won an Oscar for *The Untouchables* (1987) and has also given fine performances in such films as Hitchcock's *Marnie* (1964), *The Hill* (1965), *The Man Who Would be King* (1975), *Robin and Marian* (1976), *Cuba* (1979) and *The Name of the Rose* (1987). Knighted in New Year Honours, 2000.

Cooper, Gary (**1901–61**)

Cooper embodied quintessential American decency—not blustering like Wayne nor cynical like Bogart. His most famous roles are as the decent lad up from the country putting sophisticates to shame in *Mr. Deeds Goes to Town* (Frank Capra, 1936), the pacifist soldier in Hawks's *Sergeant York* (1941), and the lone sheriff in Zinnemann's *High Noon* (1952) confronting four gunmen out for revenge.

Crawford, Joan (**1906–77**)

The leading unhappy-in-love female star of the thirties and early forties (as in Cukor's *The Women* of 1939), Crawford won an Oscar for *Mildred Pierce* (Michael Curtiz, 1945). In later life a successful and immensely wealthy businesswoman, she was better known perhaps as a star than for any individual performances, and as the subject of her daughter's sensational memoir, *Mommie Dearest*, filmed in 1981 with Faye Dunaway as Crawford. Played masochist to Bette Davis's sadist in *Whatever Happened to Baby Jane?* (1962).

Crowe, Russell (**b. 1964**)

Like Mel Gibson before him, Crowe established a successful film career in Australia before moving to Hollywood. Such roles as the policeman in *L.A. Confidential* (1997) and the Roman hero of *Gladiator* (2000) seemed to type him as a virile leading man of the old school, but he has also shown himself adept at character roles, such as the mentally unstable mathematician in *A Beautiful Mind* (2001) and, particularly, as the whistle-blower in Michael Mann's critique of the tobacco industry, *The Insider* (1999).

Cruise, Tom (**b. 1962**)

Of the group of young American actors who shot to fame in the 1980s and were known collectively as the "brat pack", Cruise has proved to be the most durable, combining good looks with career shrewdness. He has had his glossy hits like *Top Gun* (1986) and *Mission Impossible* (1995) but he has also, as learning experience, played unselfish supporting roles to two Oscar-winning performances—Paul Newman's in *The Color of Money* (1986) and Dustin Hoffman's in *Rain Man* (1988). The benefit of such experience can be seen in his performances in *Born on the Fourth of July* (1989), *Jerry Maguire* (1996), *Magnolia* (1999) and his work with Stanley Kubrick on that director's final film, *Eyes Wide Shut* (1999).

Davis, Bette (**1908–89**)

"Nobody's as good as Bette when she's bad" was the slogan coined for Bette Davis, who excelled at playing dynamic or queen-bitch heroines. Among her major screen performances were three for William Wyler, *Jezebel* (1938), *The Letter* (1940) and *The Little Foxes* (1941), and when her career seemed destined for oblivion in the late 1940s, she returned with one of the classic characterisations of the screen, as the dominating actress Margot Channing in *All About Eve* (1950). Her autobiography *The Lonely Life* (1962) is one of the frankest and most intelligent of any screen star.

Day, Doris (**b. 1924**)

Pure, wholesome singing star who achieved her peak of popularity in the 1950s and early 1960s, particularly in a series of romantic comedies she made with Rock Hudson, including *Pillow Talk* (1959), *Lover Come Back* (1962) and *Send Me No Flowers* (1964). Appropriated by the feminists, who admire her screen persona for its career-woman independence and its healthy suspicion of male seductive strategies. Certainly someone who can upstage performers such as James Cagney (in *Love Me or Leave Me*, 1954), James Stewart (in *The Man Who Knew Too Much*, 1956) and Clark Gable (in *Teacher's Pet*, 1958) was no mean actress.

Day-Lewis, Daniel. *See* **B19.**

Dean, James (**1931–55**)

Dean made three starring feature roles before his death in a car crash in 1955. But those three, and particularly *Rebel Without a Cause* for Nicholas Ray in 1955, were enough to establish him as Hollywood's leading rebel (along with Brando—and how fascinating subsequent rivalry between their careers would have been). In *Rebel* Dean showed himself as a gentler, more idealistic figure than Brando, particularly in his "adoption" of the young runaway Sal Mineo. In *East of Eden* (Kazan, 1955), it is again his idealism that leads him to look out his mother, now running a whore-house, with disastrous results. In *Giant* (Stevens, 1956) he is an independent cowboy whose discovery of oil on his land will transform him into an isolated tycoon.

De Niro, Robert (**b. 1943**)

Perhaps the finest American screen actor since Brando, noted for the dedication with which he immerses himself in his roles (*e.g.*, his gaining sixty pounds in weight to play the role of Jake LaMotta in decline in *Raging Bull*). He has had a particularly important collaboration with director Martin Scorsese, for whom he has turned in some of his finest studies of violent yet tortured masculinity: *Mean Streets* (1973), *Taxi Driver* (1976), *Raging Bull* (1980), *Cape Fear* (1991), *Casino* (1995). Other important films include: *The Godfather Part II* (1974), *The Deer Hunter* (1978).

Dietrich, Marlene (**1902–92**)

Overnight fame came Dietrich's way when Joseph von Sternberg cast her as the sensuous and manipulative night-club singer Lola in *The Blue Angel* (1930). She manipulates Emil Jannings's school teacher there as Sternberg's camera manipulates her (and us, the spectators), through a sequence of lushly masochistic masterpieces including *The Scarlet Empress* (1934). Her post-Sternberg career diversified into cabaret performance, and her subsequent movies, including *The Flame of New Orleans* for Rene Clair in 1941 and *Rancho Notorious* for Fritz Lang in 1952, did not attain the same heights as her work for Sternberg, though she gave striking performances in two Billy Wilder films, *A Foreign Affair* (1948) and *Witness for the Prosecution* (1957), and a memorable cameo in Welles's *Touch of Evil* (1958).

Douglas, Kirk (**b. 1916**)

Dimpled-chin he-man of the American screen, who excelled in roles of unscrupulous, ambitious anti-heroes, such as those in *Champion* (1949), *Ace in the Hole* (1951) and *The Bad and the Beautiful* (1952), though a more sensitive and tormented side to his persona is also seen in such films as *Lust for Life* (1955), in which he plays Van Gogh, and *Paths of Glory* (1957). The father of actor Michael Douglas.

Eastwood, Clint (**b. 1930**)

Eastwood is in the great tradition of stars like John Wayne and Gary Cooper who projects pure Americanism and rectifies wrongs, though in a more ferocious manner than his predecessors. Became a star for his "Man With No Name" characterisation in Sergio Leone's violent, stylised "Dollars" westerns; and became a superstar after playing the tough cop in *Dirty Harry* (1971). Sometimes attacked for their Fascist overtones, Eastwood's films have also been praised for their strong female roles, Eastwood's willingness to examine his own screen persona, and their engagement with contemporary issues. Eastwood is also a prolific director, sometimes starring in his own films (*e.g. The Outlaw Josey Wales*, 1976) and sometimes not (*Bird*, 1988), *Mystic River*, (2003). His revisionist Western *Unforgiven* (1992) was widely acclaimed as a classic and won him a directing "Oscar', as did the sensitive drama, *Million Dollar Baby* (2004). His war films, *Flags of Our Fathers* (2006) and *Letters from Iwo Jima* (2007) have also been widely acclaimed.

Fairbanks, Douglas (1883–1939)

The supreme action man of silent cinema, excelling in such features as *The Three Musketeers* (1921), *Robin Hood* (1922) and *The Thief of Bagdad* (1924). Age and sound took their toll of his popularity as did his divorce from Mary Pickford in 1936, after a marriage of sixteen years. But during the silent era, nobody epitomised screen heroism more exuberantly.

Fields, W. C. (1879–1946)

Fields is the polar opposite of Chaplin as a screen comedian, in that, while the "little fellow" courts audience affection, Fields does everything in his drunken, misogynistic, mean, cynical, ill-tempered power to repel it. Through such titles as *Mrs. Wiggs of the Cabbage Patch* (Norman Taurog, 1934) and *Never Give a Sucker an Even Break* (Edward Cline, 1941), he paraded preposterous situations (usually of his own invention), and a battery of dislikes that included wives, children, domestic animals and authority figures. His best films were *It's A Gift* (1935) and *The Bank Dick* (1940). When he was discovered on his death-bed reading the Bible, he explained that he was "looking for loopholes".

Finch, Peter (1916–77)

Rugged yet subtle screen performer, who won the British Academy Award four times for his performances in *A Town Like Alice* (1956), *The Trials of Oscar Wilde* (1960), *No Love for Johnnie* (1961) and *Sunday, Bloody Sunday* (1971). He won a posthumous Oscar for his role in *Network* (1976).

Finney, Albert (b. 1936)

Finney made a big impression with his first screen performances in such films as *Saturday Night and Sunday Morning* (1961) and *Tom Jones* (1963), and was hailed as "a second Olivier". But, unlike Richard Burton, he preferred to eschew screen stardom in favour of theatrical work. The most powerful of his later film performances has been as the drunken Consul in Huston's adaptation of Malcolm Lowry's novel, *Under the Volcano* (1984). Co-starred with Julia Roberts to fine effect in *Erin Brockovich* (2000).

Flynn, Errol (1909–59)

The swashbuckling leading man of a host of popular films. Born in Hobart, Tasmania he became an American citizen in 1942. Between 1935 and 1942 he acted in some of the most enduringly popular films of all time. These included *Captain Blood*; *The Charge of the Light Brigade*; *The Adventures of Robin Hood*; *The Dawn Patrol*; *Dodge City*; *The Sea Hawk*; *They Died With Their Boots On*; and *Gentleman Jim*. His private life ensured he was rarely out of the news. He was married three times and died aged only 50 when hard living finally caught up with him (he famously spent much of his time in bars, bed and the headlines).

He was the father of the actor and journalist Sean Flynn.

Fonda, Henry (1905–82)

One of the major Hollywood leading men of the late thirties and forties, with distinguished starring roles for Fritz Lang (as the runaway in *You Only Live Once*, 1937) and John Ford (in *Young Mr. Lincoln* and *Drums Along the Mohawk*, both 1939, and *The Grapes of Wrath* (1940). His honest and conscientious stance was just right for the immediate pre- and post-war years. After a lull in his screen career, he made a successful comeback in such films as *Mister Roberts* (1955), *Twelve Angry Men* (1957) and *The Best Man* (1964), and won a long-awaited Oscar for his last film, *On Golden Pond* (1981), co-starring with his daughter Jane.

Fonda, Jane (b. 1937)

Began her career in "sex-symbol" roles—in Hollywood and for her then husband Roger Vadim –that now appear incongruous in the light of her progressive political position (Edward Dmytryk's *Walk on the Wild Side*, 1962; Vadim's *Barbarella*, 1968). Her involvement with the women's movement and anti-Vietnam campaigns took her into such films as *Klute* (Pakula, 1971), where she plays a prostitute who regards herself as "the only truly liberated woman". She won an Oscar for *Klute* and won again later in the decade for *Coming Home* (1978).

Ford, Harrison (b. 1942)

Recently voted the world's most popular film star, a well-earned reward for an actor whose career had begun with discouraging slowness. The turning point came with his role as Han Solo in *Star Wars* (1977) and his stardom was augmented when he became Steven Spielberg's Indiana Jones, a characterisation much admired for its difficult combination of athleticism and wit. An accomplished actor in both romantic comedy and complex character roles (*e.g.* in *Witness* and *The Mosquito Coast*), he is liked best by the public as a taciturn action man of the old school, even when, as in the film *Air Force One* (1997), he also happens to be President of the USA.

Foster, Jodie (b. 1962)

Child star who has developed into one of the foremost feminist talents of the cinema. Played a precocious moll in the child gangster spoof, *Bugsy Malone* (1976) and then created a furore with her role as an under-age prostitute in *Taxi Driver* (1976), fanned even further when an attempted assassination of President Reagan was said to have been inspired by the gunman's infatuation with Foster's role in that movie. She survived the attendant notoriety to develop into one of the modern screen's most adventurous actresses, winning Oscars for her performances as a rape victim in *The Accused* (1988) and a feisty female investigator in *Silence of the Lambs* (1991). She can direct too.

Gable, Clark (1901–60)

Gable was Hollywood's number one heartthrob in the years immediately preceding the war. His open-handed cheerfulness and easy-going Americanism now might appear dated, but they bowled over a long list of leading ladies, including Claudette Colbert (in Frank Capra's *It Happened One Night*, 1934) and Vivien Leigh (in the Fleming/Cukor/Wood success *Gone with the Wind*, 1939). He is proof that Hollywood male chauvinism did not need the bullying qualities of a John Wayne to make its mark. He gave perhaps his greatest performance in his last film, *The Misfits* (1961).

Garbo, Greta (1905–90)

A career that lasted only seventeen years and a reclusive retirement combined to create the "Garbo myth" of world-weary, capricious and lonesome sensuality, which must be one of the most potent in cinema history. She moved from Sweden to Hollywood under the aegis of the director Mauritz Stiller in 1926, to become MGM's major star, whose every move was heralded by a barrage of studio publicity (thus, "Garbo talks!" before Clarence Brown's *Anna Christie* in 1930, and "Garbo laughs!" before *Ninotchka*, made for Ernst Lubitsch in 1939). Unlike her romantic co-star in the silent period, John Gilbert, Garbo triumphantly made the transition to talkies, her greatest successes being in *Queen Christina* (1934) and *Camille* (1937). But after the disaster of *Two-Faced Woman* (1941) she retired.

Garland, Judy (1922–69)

A prominent teenage star who became famous through her performance in *The Wizard of Oz* (Victor Fleming, 1939), where she first performed the song whose soaring yearning was to become her hallmark—"Over the Rainbow". She starred in musicals for her then-husband, Vincente Minnelli (including *Meet Me in St. Louis*, 1944), but the pattern of breakdown, emotional turmoil, and abuse of barbiturates had set in by the beginning of the fifties. Stage appearances and nervous breakdowns between them crowded out her mature film career, though her performance in *A Star is Born* (1954) was a tour-de-force.

Gibson, Mel (b. 1956)

'The most interesting young actor of his period,' said Franco Zeffirelli when casting Mel Gibson as Hamlet. An odd role ostensibly for the star of action extravaganzas like *Mad Max* (1979) and *Lethal Weapon* (1987) but then again, perhaps not: all are heroes unhinged by violent destruction of their family lives and who affect an antic disposition to cope with their torment. Gibson is good at character extremes, as well as being a competent director and a glamour film star of a kind rarely seen since the 1930s. Though actually born in New York, his first film successes were in Australia, but like director Peter Weir, for whom he starred in *Gallipoli* (1981) and *The Year of Living Dangerously* (1983), he moved to Hollywood in the early 1980s and has not looked back. Won a directing Oscar for *Braveheart* (1995) and created enormous controversy with a personal project inspired by his religious beliefs, *The Passion of the Christ* (2004).

Gish, Lillian (1896–1993)

The longest career of movie actors—from D. W. Griffith's *An Unseen Enemy* (1912) through to Lindsay Anderson's *The Whales of August* (1987). She radiated innocence for Griffith in *The Birth of a Nation* (1915) and *Intolerance* (1916), before leaving his Biograph company to make more money, first for Inspiration and then for MGM. During the sound era, her screen appearances were intermittent, though she was particularly effective as the brave schoolma'am facing up to Robert Mitchum's demonic preacher in *The Night of the Hunter* (1955). Her performances in Griffith's *Broken Blossoms* (1919) and Victor Seastrom's *The Wind* (1928) are among the greatest of the silent film era.

Grant, Cary (1904–86)

His British origin shows in his debonair style and curious "mid-Atlantic" accent (imitated by Tony Curtis in Billy Wilder's *Some Like it Hot*, 1959). Beneath his gentlemanly urbanity, frenzy, even insanity, never seem far away, which accounts for the matchless ambiguity of his greatest performances—as the suspected wife-murderer in Hitchcock's *Suspicion* (1941), as baiting foil to Mae West in Wesley Ruggles's *I'm No Angel* (1933), as advertising man pursued across America by spies in *North by North-West* (Hitchcock, 1959), and above all the victim of the insecurity that stems from sex-stereotyping in the comedies he made opposite various leading ladies for Howard Hawks—*Bringing Up Baby* (with Katharine Hepburn, 1938), *His Girl Friday* (with Rosalind Russell, 1940), and *I Was a Male War Bride* (with Ann Sheridan, 1949). Small wonder that he won an Oscar in 1970 for "sheer brilliance".

Guinness, Sir Alec (1914–2000)

Guinness came to prominence as a screen actor in the great Ealing comedies, notably *Kind Hearts and Coronets* (1949), *The Man in the White Suit* (1951), *The Lavender Hill Mob* (1952), and *The Ladykillers* (1955). He also developed a close working relationship with David Lean, and won an Oscar for his superb performance in Lean's *The Bridge on the River Kwai* (1957). An actor of unobtrusive subtlety and infinite resource, he achieved his biggest popular success in *Star Wars* (1977) but more representative of his skills were his masterly characterisations in such films as *Tunes of Glory* (1960) and *Little Dorritt* (1987).

Hackman, Gene (b. 1931)

One of the most durable and dependable character stars of modern American cinema., at home in comedy but at his best when giving subtle emotional colouring to 'average' men with a darker side to their natures. His most famous role is still probably that of the rebellious rule-breaking cop, 'Popeye' Doyle in *The French Connection* (1971), for which he won an Oscar, as he did also for his performance as the sadistic sheriff in Clint Eastwood's *Unforgiven* (1992). But his great performances are legion: *The Conversation* (1974), *Night Moves* (1975), *Eureka* (1982), *Under Fire* (1983), *Target* (1985), *Mississippi Burning* (1988), *Class Action* (1991).

Hanks, Tom (b. 1956)

Popular leading man of the last decade in both comedy and dramatic roles, who became the first actor since Spencer Tracy to win the Best Actor Oscar in consecutive years: for *Philadelphia* (1993) and *Forrest Gump* (1994). His acceptance speeches have become something to be feared, however: in one, he inadvertently 'outed' a former drama teacher. Other key films: *Big* (1988), *Sleepless in Seattle* (1993), *Apollo 13* (1995), *Saving Private Ryan* (1998) and *Road to Perdition* (2002).

Hepburn, Audrey (1929–93)

Enchanting elfin actress who won an Oscar in her first starring role, *Roman Holiday* (Wyler, 1953). She then proceeded to bewitch some of Hollywood's most eminent senior citizens—Humphrey Bogart in *Sabrina* (1954), Gary Cooper in *Love in the Afternoon* (1957), Cary Grant in *Charade* (1963), Rex Harrison in *My Fair Lady* (1964). An adept comedienne, she also proved herself a formidable dramatic actress in *The Nun's Story* (1959), *The Children's Hour* (1961) and *Robin and Marian* (1976). She then virtually retired though Spielberg cast her appropriately as an angel in *Always* (1989).

Hepburn, Katharine (1909–2003)

The most intelligent and astringent of all screen comediennes—if not all screen actresses. She remained resolutely outside the mould of female stardom, regarded for years as box-office poison and relying on her mind rather than her body for impact. Her most celebrated films are those made with her long-time off-screen lover, Spencer Tracy—notably *Adam's Rib* and *Pat and Mike* for George Cukor (1949 and 1952 respectively), and *State of the Union* for Frank Capra in 1948. But her warm sharpness was equally in evidence with Cary Grant (*Bringing Up Baby* for Hawks in 1938) and Humphrey Bogart (*The African Queen* for John Huston in 1951).

Winner of four best actress Oscars (more than any other recipient), she published a set of autobiographical memoirs, *Me* (1991). Her greatest screen performances include *Alice Adams* (1935), *Summer Madness* (1955), *Suddenly Last Summer* (1959) and *Long Day's Journey into Night* (1962).

Heston, Charlton (1923–2008)

Heston's first starring role was in C. B. DeMille's circus epic, *The Greatest Show on Earth* (1952). He later specialised in epic roles, bringing dignity and integrity to the genre, particularly in his title performances in *Ben Hur* (1959) and *El Cid* (1961). His historical roles ranged from Cardinal Richelieu to General Gordon, from Moses to Michelangelo: his best modern film role was probably in Welles's *Touch of Evil* (1958). He also excelled in westerns, in *The Big Country* (1958) and *Will Penny* (1968).

Hoffman, Dustin (b. 1937)

Earnest, intense method actor whose perfectionism has sometimes driven co-stars to distraction (Olivier: "Dustin is very talented—but why doesn't he just act?") but has certainly produced the goods—Oscars for his performances in *Kramer vs. Kramer* (1979) and *The Rain Man* (1988). Other important roles: *The Graduate* (1967), *Lenny* (1974), *All the President's Men* (1976), and *Tootsie* (1982). Now a film director (*e.g. Quartet*).

Holden, William (1918–81)

Handsome leading man of the 1940s rescued from bland B-picture roles by Billy Wilder, who cast him as a screen writing gigolo in *Sunset Boulevard* (1950) and as a captive capitalist in *Stalag 17* (1953), for which Holden won an Oscar. After a lean spell in the 1960s, his career revived with his splendid leading performance in *The Wild Bunch* (1969), and before his death, he gave further thoughtful characterisations in *Network* (1976) and *Fedora* (1978). Other key roles: *Golden Boy* (1939), *Sabrina* (1954), *Picnic* (1955) and *The Bridge on the River Kwai* (1957).

Hopkins, Sir Anthony (b. 1937)

Theatrically trained, Hopkins is sometimes seen as the natural successor to Richard Burton and Sir Laurence Olivier: indeed, he dubbed Olivier's voice when *Spartacus* was re-released in an extended version. For all his versatility and skill, however, he seems likely to be remembered most for his performance as a monster, the cannibalistic Hannibal Lecter in *The Silence of the Lambs* (1991). Other key performances: *The Lion in Winter* (1968), *Juggernaut* (1974), *The Elephant Man* (1980), *The Bounty* (1984), *Howards End* (1992), *The Remains of the Day* (1993), *Nixon* (1995), *Amistad* (1997).

Howard, Trevor (1916–87)

Leathery character actor of the British cinema, reputedly Graham Greene's favourite. Capable of acting just about anyone off the screen, which might be the reason that he only rarely got the parts (and therefore the recognition) that he deserved. Important films include: *Brief Encounter* (1945), *The Third Man* (1949), *Outcast of The Islands* (1951), *The Key* (1958), *Sons and Lovers* (1960), *Mutiny on the Bounty* (1962) and *Ludwig* (1972).

Hudson, Rock (1925–85)

Solid Hollywood leading man who sprang back into the public eye in the 1980s because of his death from AIDS. This rather contradicted his screen image as the all-American romantic hero. An effective screen actor in dramas such as *Giant* (1956) or comedies such as *Send Me No Flowers* (1964), he had, in retrospect, his most resonant role in John Frankenheimer's sci-fi horror film, *Seconds* (1966), where a dissatisfied middle-aged man fakes his own death and, through plastic surgery, starts a new life looking like Rock Hudson—and finds that soul-destroying also.

Huppert, Isabelle (b. 1955)

She came to prominence with a beautiful performance in *The Lacemaker* (1977), playing an unaffected girl whose emotional vulnerability leads to a complete mental breakdown after an unhappy love affair. The fragility seemed so natural and believable that one has since been often taken aback by her range and resource, particularly in some of her films for Claude Chabrol, where she has revealed surprising ferocity behind the freckle-faced exterior. Her performance in Michael Haneke's *The Piano Teacher* (2001), where she plays a music teacher with secret sado-masochistic tendencies, is a *tour-de-force*.

Jannings, Emil (1884–1950)

A king of the German silent cinema, but ruined by the coming of sound (which showed up his thick accent) and also his collaboration with the Nazis. His massive self-sentimentalisation and Prussian obsession with lost status were triumphant in Murnau's *The Last Laugh* (1924), and even more so in his role as the puritanical schoolteacher Professor Rath, destroyed by his passion for Marlene Dietrich's Lola in Sternberg's *The Blue Angel* (1930). This performance remains the greatest monument of male sexual humiliation in cinema history. He epitomised silent film acting at its most Expressionist and expressive, though Luis Buñuel said he preferred Buster Keaton.

Karloff, Boris (1887–1969)

Here again on- and off-screen personas interacted intriguingly. Mild mannered English cricket-loving gentleman William Henry Pratt became the best-known horror star in Hollywood history with his performance as the blundering yet tender-hearted monster in James Whale's *Frankenstein* in 1931. Thenceforth his legendary status was secure, and augmented by his work for Karl Freund (*The Mummy* of 1932) and Charles Vidor (*The Mask of Fu Manchu*, 1932). As moving as his performance in *Frankenstein* in many ways is his valedictory appearance in Peter Bogdanovich's *Targets* (shot in the year of his death) where he plays a retired Hollywood horror star whose essential kindness is appalled by the horror of American society.

Keaton, Buster (1895–1966)

Arguably the greatest director and the greatest actor of the American silent era. As an actor, Keaton's deadpan appearance, often almost suicidal insistence on choreographing and carrying out all his own stunts, and awareness of the element of fantasy identification in cinema have ensured that his performances remain consistently exciting and do not date. As a director, he masterfully exploited the relationship between man and machine—driver/train and actor/camera—in *The General* of 1926, and that between cinema and dream in *Sherlock Junior* of 1924. His career was undermined as much by the classic Hollywood afflictions—marital problems and drinking—as by the coming of sound.

But his reputation has soared since his death, and works such as *Our Hospitality* (1923), *Seven Chances* (1925), *The Navigator* (1927) and *Steamboat Bill Jr.* (1928), along with his aforementioned films, are now regarded as comedy classics. Appeared alongside Chaplin in an unforgettable routine in the latter's *Limelight* (1952).

Kelly, Gene (1912–96)

The most inventive and adventurous actor-choreographer of the American screen. Rival to Fred Astaire as Hollywood's dancing master, Kelly was even more creative in furthering the boundaries of the film musical, particularly in a trio of magnificent musicals he co-directed with Stanley Donen: *On the Town* (1949), *Singin' in the Rain* (1952) and *It's Always Fair Weather* (1955).

Kelly, Grace (1928–82)

Aloof but elegant leading lady who made her first major impression as Gary Cooper's Quaker wife in *High Noon* (1952) and then as the archetypal Hitchcockian ice-cool blonde in *Dial M for Murder* (1954), *Rear Window* (1954) and *To Catch a Thief* (1955). Her dramatic prowess was revealed in her Oscar-winning role in *The Country Girl* (1954) but she gave up stardom for royalty when she married Prince Rainier of Monaco in 1956.

Kerr, Deborah (1921–2007)

One of the most versatile and sensitive of British screen actresses, whose persona of "English rose" was changed when she played the nymphomaniac wife of an Army Captain in *From Here to Eternity* (1953). She seemed at her finest either when playing nuns with a hint of neurosis—*Black Narcissus* (1947), *Heaven Knows, Mr. Allison* (1957)—or prim teachers or governesses wrestling privately with emotional repression—*The King and I* (1955), *Tea and Sympathy* (1956), *The Innocents* (1961).

Kidman, Nicole (b. 1968)

Formerly married to Tom Cruise, she seems to share Cruise's ability to choose her roles with some shrewdness. As a consequence, she has matured into a screen actress of considerable subtlety and force. She won an Oscar for her portrayal of Virginia Woolf in *The Hours* (2002). Other important films: *Dead Calm* (1989), *Malice* (1993), *To Die For* (1995), *Portrait of a Lady* (1996), *Eyes Wide Shut* (1999), *Moulin Rouge* (2001), *The Others* (2001) and *Dogville* (2003).

Lancaster, Burt (1913–94)

Acrobat turned actor, who revealed a sensitive interior behind his action-man mask. He won an Oscar for his role as a religious charlatan in *Elmer Gantry* (1960), and a Venice Festival award for a more introvert performance in *Bird Man of Alcatraz* (1962). "A deeply mysterious man" was the verdict on him of Luchino Visconti, who directed him to great effect in *The Leopard* (1963) and *Conversation*

Piece (1974), and he triumphed also under Louis Malle in *Atlantic City* (1980). He had a career of fascinating contrasts, between swashbuckling and sensitive roles. Other key films include: *The Killers* (1946), *The Crimson Pirate* (1952), *From Here to Eternity* (1953), *Sweet Smell of Success* (1957), *1900* (1976) and *Twilight's Last Gleaming* (1977).

Laughton, Charles (1899–1962)

Bulky actor of phenomenal power and range, with the occasional tendency to ham but also capable of producing magical effects with a sympathetic director. It is sometimes thought that his heyday was in the thirties, when he excelled in *The Private Life of Henry VIII* (1933), *Ruggles of Red Gap* (1935), *Mutiny on the Bounty* (1935) and *The Hunchback of Notre Dame* (1939). But he was no less remarkable in later films such as *Hobson's Choice* (1953), *Witness for the Prosecution* (1957), *Spartacus* (1960) and *Advise and Consent* (1962). There is a sense of relish about his greatest acting, whether playing saint or sadist. One should not forget also his one and only film as director, an altogether remarkable, poetic thriller *The Night of the Hunter* (1955) that constitutes one of the most extraordinary directing debuts in cinema history.

Laurel (1890–1965) **and Hardy** (1892–1957)

The first great comedy partnership in films, and never surpassed. Their films usually involve frantic attempts to gain social acceptance (*e.g.* as piano-movers or salesmen), that lead to the disasters ruefully described by Hardy as "another nice mess". Their features, including *Pack Up Your Troubles* (Marshall and Raymond McCarey, 1932) and *A Chump at Oxford* (Alfred Goulding, 1940), retain the personas—sly and skinny Stan and overweight Ollie trying to cling on to his dignity—almost intact. The comedy of failure in its purest, most unpretentious form. Key films include: *Big Business* (1929), *The Music Box* (1932), *Sons of the Desert* (1934), *Way Out West* (1937).

Leigh, Vivien (1913–67)

Fragile and exquisite English actress who remarkably scored her greatest film triumphs in two quintessentially American roles: as Scarlett O'Hara in *Gone With the Wind* (1939) and as Blanche DuBois in *A Streetcar Named Desire* (1951). Married to Laurence Olivier in 1940, her later career was blighted by physical and mental illness. She was divorced from Olivier in 1960, and her last major film roles were in *The Roman Spring of Mrs. Stone* (1961) and *Ship of Fools* (1965).

Lemmon, Jack (1925–2001)

Consummate film actor who is probably most associated in the public mind with a series of sublime comedy characterisations in films of Billy Wilder, such as *Some Like it Hot* (1959), *The Apartment* (1960), *The Fortune Cookie* (1966), and *Avanti!* (1972). But he was an equally forceful straight actor, as films such as *Days of Wine and Roses* (1962), *The China Syndrome* (1979), *Missing* (1982) and *Glengarry Glen Ross* (1992) demonstrate. The screen's best tragi-comedian since Chaplin.

Loren, Sophia (b. 1934)

Epitomises the stereotype of Latin female sexuality for the moviegoer, much as Marcello Mastroianni did for the male. She began for Hollywood in ripely sensual roles (e.g. *Desire under the Elms* for Delbert Mann in 1958), before moving on to more demanding dramatic parts, such as Vittorio de Sica's *Two Women* for which she won an Oscar in 1961.

Lorre, Peter (1904–64)

Among his best-known films there is only one in which he actually starred: *M* for Fritz Lang in 1931, where he portrayed a demented child-murderer, contorting his features as much as Lang's direction contorted the screen images. But he became one of Hollywood's most memorable supporting actors, as the crazed hitman in Huston's *The Maltese Falcon* (1941), and for Michael Curtiz (in *Casablanca* of 1943 and *Passage to Marseilles* of 1944) and Frank Capra (*Arsenic and Old Lace*, 1944). Like Karloff but in a very different way, he excelled at suggesting sensitivity beneath the contortions of horror and malice.

Maclaine, Shirley (b. 1934)

Prodigiously talented dancer-cum-comedienne-cum dramatic actress. Won an Oscar for *Terms of Endearment* (1983), but her best films are the early ones: *The Trouble With Harry* (1955), *Some Came Running* (1958), *The Apartment* (1960), *The Children's Hour* (1961) and *Sweet Charity* (1969).

March, Fredric (1897–1975)

One of Hollywood's finest character actors, particularly when portraying ostensibly decent men with darker sides to their personalities. This was shown to particular effect in *Dr. Jekyll and Mr. Hyde* (1932) but was also a feature of some other of his major roles: *Les Miserables* (1935), *The Best Years of our Lives* (1946), *Death of a Salesman* (1952), *Executive Suite* (1954), *The Desperate Hours* (1955) and *Inherit the Wind* (1960).

Marx Brothers: Chico (1887–1961), **Harpo** (1888–1964), **Groucho** (1890–1978)

Hollywood's undisputed great comic family. Groucho's undammable flow of insult and wisecrack, Chico's illogicalities and prevarications (delivered in a heavy mock-Italian accent), and Harpo's mute mime form an unbeatable trio, whether in the early Paramount features (such as *Duck Soup* for Leo McCarey in 1933) or in their later work for MGM, where musical and romantic interludes irksomely break up the stream of comedy (as in *A Day at the Races*—Sam Wood, 1937). Their most popular film, and Groucho's favourite, was *A Night at the Opera* (1935). (Another brother Zeppo appeared in some of their earlier films, either as an improbable romantic lead or even, in *Horse Feathers* of 1932, as Groucho's son.)

Mason, James (1909–84)

Mason's style migrated successfully from the British industry (as in *Odd Man Out*—Carol Reed, 1947) to Hollywood and the international circuit. He was an urbane villain for Hitchcock in *North by North-West* (1959), and a suitable articulate and obsessed lover for *Lolita* (Stanley Kubrick, 1962), somewhat removed from the persona of the romantic sadist with which he had first shot to fame (in *The Man in Grey*, 1943 and *The Wicked Lady*, 1945). One of those screen actors like Trevor Howard or David Niven who seemed incapable of giving a bad performance, however bad the film was around him. When the film was good—like, say, *Five Fingers* (1952), *A Star is Born* (1954), *The Pumpkin Eater* (1964), *The Verdict* (1982)—he could be quite exceptional.

Mastroianni, Marcello (1924–96)

The ultimate listless Latin lover, who seems wearied by the very thought of all the women to whom he is supposed to appeal. This quality in fact enables his screen persona to work quite subversively against the macho ideal of Hollywood, as in Fellini's *La Dolce Vita* (1960), where he plays a disillusioned journalist, or Antonioni's *La Notte* (1961), as the exhausted husband of Jeanne Moreau. His finest performance remains that in Fellini's *8½* (1963), as the film director (an obvious alter ego to Fellini), whose very prostration and inability to organise his neuroses into cinematic form at the end provide the mainspring that enables him to do so. The films with Fellini and Antonioni remain his best-known work. His later successes included *Macaroni* (1985), opposite Jack Lemmon; *Ginger and Fred* (1986), for Fellini; and a particularly intense performance in *The Beekeeper* (1986) for Greece's major contemporary director, Theo Angelopoulous.

McQueen, Steve (1930–80)

Supercool but smouldering anti-hero and loner, McQueen became a star after his POW antics on a motorbike in John Sturges' *The Great Escape* (1963). Best remembered for action roles like *The Magnificent Seven* (1960) or *Bullitt* (1968), McQueen was showing signs of greater artistic ambition towards the end of his life, producing as well as starring in an adaptation of Ibsen's *An Enemy of the People* (1979) and contributing a finely shaded, poignant performance in the elegiac Western, *Tom Horn* (1980).

Mifune, Toshiro (1920–97)

Japanese actor whose robust style, ironic as well as dramatic, was indelibly associated with the films he made for Kurosawa, including *Rashomon* (1951), *Seven Samurai* (1954), *Throne of Blood* (1957) and *Yojimbo* (1961). He also appeared in the occasional Hollywood film, most notably opposite Lee Marvin in *Hell in the Pacific* (1969).

Mitchum, Robert (1917–97)

A deceptively outstanding film actor whose lazy style concealed enormous range and prodigious depth. Directors as exacting as John Huston (*Heaven Knows Mr. Allison*, 1957) and Fred Zinnemann (*The Sundowners*, 1960) testified to Mitchum's exceptional abilities. Only once nominated for an Oscar (for *The Story of G.I. Joe*, 1945), his memorable performances include *Pursued* (1947), *Build My Gallows High* (1947), *The Lusty Men* (1952), *The Night of the Hunter* (1955), *Cape Fear* (1962), *Ryan's Daughter* (1970), *The Friends of Eddie Coyle* (1973), *The Last Tycoon* (1976).

Monroe, Marilyn (1926–62)

Not the original cinematic sex symbol—that distinction belongs to Mary Pickford or Rudolph Valentino—but Monroe is certainly the best-known. Nowhere else have the on-and-off screen persona interacted to such devastating, and finally destructive, effect. She began as a "dumb blonde" in the early fifties before producers and directors recognised in her vulnerability and ambivalent attitude towards her own sexuality—pride tempered by the desire to be appreciated for something more—outstanding qualities. Her best films remain comedies in which her ambivalence was played upon to enrich the texture of the movies: *Bus Stop* for Joshua Logan in 1956, and for Billy Wilder, *The Seven-Year Itch* of 1955, and *Some Like It Hot* in 1959. She gave an extraordinary dramatic performance in Huston's *The Misfits* (1961), but was dismissed from her final project (Cukor's *Something's Got to Give*) for unreliability in 1962, and not long afterwards committed suicide. Revelations of her off-screen loneliness and the mysterious circumstances of her death went to fuel what is still Hollywood's most potent and macabre legend.

Moreau, Jeanne (b. 1928)

Described as the "thinking man's actress', and whose name was synonymous with some of the greatest and most controversial European art movies of the late fifties and early sixties: Malle's *The Lovers* (1958), Truffaut's *Jules et Jim* (1961), Antonioni's *La Notte* (1962) and Buñuel's *Diary of a Chambermaid* (1964).

Newman, Paul (1925–2008)

Blue-eyed boy of modern American film, exceptionally good looking and a considerable actor to boot. Early Oscar-nominated performances in *Cat on a Hot Tin Roof* (1958), *The Hustler* (1961), *Hud* (1963) and *Cool Hand Luke* (1967) testified to Newman's great skill in revealing an attractive, adventurous side to roles which, in other hands, could have seemed unsympathetic and morbid. He finally won his Oscar for *The Color of Money* (1986), Scorsese's sequel to *The Hustler*. He also proved himself a sympathetic director, particularly of his actress-wife Joanne Woodward, in films such as *Rachel, Rachel* (1968) and *The Glass Menagerie* (1987).

Nicholson, Jack (b. 1937)

Nicholson broke into public prominence with his performance as the alcoholic ne'er-do-well in Hopper's *Easy Rider* (1969), and has remained at the top ever since with sardonic yet often tender performances. The versatility that often goes with understatement has enabled him to give outstanding performances as a drop-out classical musician (Bob Rafelson's *Five Easy Pieces* in 1970), a private eye (Polanski's *Chinatown* in 1974), a rebel in a mental hospital (Milos Forman's *One Flew Over The Cuckoo's Nest*, 1975), a cynical writer (James L. Brooks' *As Good as it Gets*, 1997) a retired cop (*The Pledge*, 2001), and a widower reappraising his life (*About Schmidt*, 2002).

Olivier, Sir Laurence (1907–89)

Perhaps the most exciting and respected actor of his generation, Olivier will first be remembered and revered for his achievement as actor and director in bringing Shakespeare to vivid life on screen with *Henry V* (1944), *Hamlet* (1948) and *Richard III* (1955). But his most subtle screen acting was to be found in two films he made for Wyler, *Wuthering Heights* (1939) and *Carrie* (1952), and one for Hitchcock, *Rebecca* (1940). His last major film role was in Mankiewicz's *Sleuth* (1972).

Pacino, Al (b. 1940)

Born in New York of Sicilian descent and an apostle of the great acting teacher Lee Strasberg, Pacino shot to prominence with his performance as Michael Corleone in *The Godfather* (1972), a role he was to repeat and refine in two sequels. An actor of great resource and range, he rivals DeNiro as the most admired American screen actor since Marlon Brando. Key films include: *Godfather II* (1974), *Dog Day Afternoon* (1975), *Scarface* (1983), *Glengarry Glen Ross* (1992), *Heat* (1996), *Looking for Richard* (1996), *The Insider* (1999) and *Insomnia* (2002).

Peck, Gregory (1916–2003)

Archetypal screen symbol of liberal integrity, particularly embodied in his performance as the lawyer defending an unjustly accused Negro in *To Kill a Mockingbird* (1962), for which he justly won an Oscar. Other important films: *Gentleman's Agreement* (1947), *The Gunfighter* (1950), *Roman Holiday* (1953), *Moby Dick* (1956), *The Big Country* (1958), *The Stalking Moon* (1968) and *I Walk the Line* (1970).

Pickford, Mary (1893–1979)

The sentimentality of Pickford's early performances for D. W. Griffith between 1909 and 1912, and her peak period as "America's Sweetheart" when married to Douglas Fairbanks (*Daddy Long Legs* for Marshall Neilan in 1919, *Pollyanna* for Paul Powell in 1920) are considerably less interesting today than her ideological role as what Basil Wright has dubbed the "hearth goddess" of domesticity and her early status as one of the first multi-millionaire film stars.

Poitier, Sidney (b. 1924)

Ground-breaking black actor, one of the first to attain Hollywood star status. Poitier won an Oscar for a now virtually forgotten movie, *Lilies of the Field* (1963), and is better remembered for such films as *The Defiant Ones* (1958), *In The Heat of the Night* (1967) and *Guess Who's Coming to Dinner* (1967). Also an accomplished director, though definitely in the commercial mainstream rather than in the radical alternative lane chosen by the new generation of black American directors such as Spike Lee and John Singleton.

Rains, Claude (1889-1967)

Soft-spoken, diminutive actor whose first screen triumph was in a part in which his face was only shown in the very last shot: namely, the eponymous hero of *The Invisible Man* (1932). A favourite co-star of Bette Davis, he was incomparable at portraying suave villainy, notably in *The Adventures of Robin Hood* (1938) and, of course, *Casablanca* (1943), but, for all his seeming dryness, he could also give uncommon intensity to the feelings of scorned love: his performances as the humiliated husbands in Hitchcock's *Notorious* (1946) and Lean's *The Passionate Friends* (1949) throb with a poignant romantic anguish.

Redford, Robert (b. 1937)

Redford is distinguished from his "peer-group" stars such as Beatty and Nicholson by a resolute rejection of the trappings of stardom. Athletically handsome (like John Wayne he went to university on a sports scholarship), he struck gold with *Butch Cassidy and the Sundance Kid* (George Roy Hill, 1969), and created perhaps his most successful dramatic role in the Scott Fitzgerald adaptation, *The Great Gatsby* for Jack Clayton in 1974. His directing debut, *Ordinary People* (1980) won him an Oscar.

His most lasting monument might well be the Sundance Institute, which he founded in 1980 and which has since become a training ground and launching pad for some of America's finest young independent film makers.

Roberts, Julia (b. 1967)

Former model who has developed into one of the star actresses of modern cinema, culminating in her critically acclaimed, Oscar winning performance in *Erin Brockovich* (2000). Other key films: *Pretty Woman* (1990), *Sleeping with the Enemy* (1990) and *Everyone Says I Love You* (1996).

Robinson, Edward G. (1893–1973)

Robinson made his name in gangster film roles such as *Little Ceasar* (1931) and as Johnny Rocco in Huston's *Key Largo* (1948). But he was actually a highly skilled actor in a variety of parts, at his best perhaps in two psychological dramas for Fritz Lang, *Woman in the Window* (1944) and *Scarlet Street* (1945); as the insurance investigator in Wilder's *Double Indemnity* (1944); and as a roguish diamond smuggler in Mackendrick's *Sammy Going South* (1963).

Schwarzenegger, Arnold (b. 1947)

Born in Graz, Austria, Schwarzenegger was a champion body-builder before he turned to acting in roles that exploited both his physique and his robotic histrionics. His persona has essentially been that of a slow-witted, thickly accented superhero whose muscle power far exceeds his intellect, and he has maintained a mass following not only through his screen heroics but also a genial willingness to poke fun at his own image. Married to the niece of President of John F. Kennedy, he was elected Republican Governor of California.

Other major films: *Stay Hungry* (1976), *Conan the Barbarian* (1982), *The Terminator* (1984) and *Total Recall* (1990).

Scott, George C. (1926–99)

On his day, one of the screen's most powerful and exciting actors. His first important role was as a razor-sharp prosecutor in Preminger's *Anatomy of a Murder* (1959), putting James Stewart on his mettle, and he followed it with an equally incisive characterisation as the sinister, Mephistophelian gambler in *The Hustler* (1961) who covets Paul Newman's soul. A dazzling comic turn as a war-mongering General in Kubrick's *Dr Strangelove* (1964), contemplating global annihilation with a sort of maniacal glee, revealed his acting range, as did his subtle, moving performance in Richard Lester's *Petulia* (1968) as a doctor experiencing a mid-life crisis in a late 1960s America that is itself about to implode. As forthright off the screen as on, he turned down his Oscar for *Patton* (1970) out of distaste for what he called the demeaning "meat parade" of the Awards ceremony.

Sharif, Omar (1932–2015)

The smouldering Egyptian actor forever famous for his roles in *Lawrence of Arabia* and *Doctor Zhivago*, where he played the title role. He was born in Alexandria. His image was of the gambling bridge-playing playboy.

Signoret, Simone (1921–85)

Classy French actress who excelled at playing lovelorn women, most memorably in Jacques Becker's *Casque d'Or* (1952) and Jack Clayton's *Room at the Top* (1959). Among her other important films are *La Ronde* (1950), *Les Diaboliques* (1955), *The Army of the Shadows* (1969) and *Madame Rosa* (1977).

Stanwyck, Barbara (1907–90)

Vibrant, strong actress, much appreciated by directors such as Capra, DeMille, Lang, Sirk for her utter professionalism. Her stock-in-trade was as a hard-as-nails heroine who knew her own mind and was sometimes not to be trusted. Nominated for an Oscar four times without winning (for *Stella Dallas*, 1937; *Ball of Fire*, 1942; *Double Indemnity*, 1944; and *Sorry, Wrong Number*, 1948), she was finally given an honorary Oscar in 1982. Other key films: *The Bitter Tea of General Yen* (1933), *Annie Oakley* (1935), *The Lady Eve* (1941), *The Furies* (1950), *There's Always Tomorrow* (1956).

Stewart, James (1908–97)

Directors found complex uses for the slow drawl and shy demeanour of this adroit screen actor: all-American integrity, in his films for Capra (*Mr. Smith goes to Washington*, 1939; *It's A Wonderful Life*, 1946); seething inner intensity in his Anthony Mann westerns; and romantic vulnerability in his Alfred Hitchcock movies, most disturbingly and tragically so in *Vertigo* (1958). A versatile performer, who combined exceptional dramatic power, seen at its best in Preminger's *Anatomy of a Murder* (1959), with a flair for comedy: his performance in Cukor's *Philadelphia Story* (1940) won him an Oscar.

Streep, Meryl (b. 1951)

One of the leading ladies of the modern screen, who at one stage seemed to snatch all the big parts, whether they were English, Danish, Polish, or Australian, let alone American. She might not always move the heart, but the acting intelligence and technique are formidable. Her key films include: *The Deer Hunter* (1978), *Kramer Vs. Kramer* (1979), *The French Lieutenant's Woman* (1981), *Sophie's Choice* (1982), *Out of Africa* (1985), *The Bridges of Madison County* (1995), *The Hours* (2002), *Mamma Mia!* (2008) and *The Iron Lady* (for which she won a Best Actress Oscar).

Swanson, Gloria (1897–1983)

Perhaps the most glamorous of silent screen stars, particularly in her films for Cecil B. DeMille, like *Male and Female* (1919). She lost much of her wealth when producing *Queen Kelly* (1928), a film she stopped in mid-production owing to director Erich von Stroheim's extravagance: and talkies proved a problem. However, she made a triumphant return to the screen as Norma Desmond in Billy Wilder's *Sunset Boulevard* (1950), as the former silent star dreaming of a comeback. When the brash screenwriter says she used to be big, she snaps back: "I *am* big. It's the pictures that got small."

Tati, Jacques (1908–82)

Like Keaton, Tati's claim to fame is based on his direction as much as on his acting. Indeed it could be said that the two in a sense came into conflict in his later career, his directorial skill and concern with elaborate mechanised set-pieces causing his output to be irregular and often working against his lanky, absent-minded quality as a clown. *Mr. Hulot's Holiday* (1953) remains one of the greatest silent comedies in cinema history (sound was actually added after shooting, but its contribution to the comic impact is minimal), and Tati's greatest achievement in that film is perhaps the way in which he manages to render a specifically French social stereotype—the would-be sporting bourgeois on a seaside holiday—appealing to a much wider audience. Later films like *Mon Oncle* (1958), *Playtime* (1968) and *Traffic* (1971) have an almost mathematical precision in their comedy lay-out and a serious underlying theme: the decline of individuality in an age of mechanisation.

Taylor, Dame Elizabeth (1932–2011)

Taylor started out as a child-star in Clarence Brown's *National Velvet* (1944) before becoming one of the major Hollywood sex symbols of the fifties, dark and sultry in Richard Brooks's *Cat on a Hot Tin Roof* (1958) and Mankiewicz's *Suddenly Last Summer* (1959). After her marriage to Richard Burton off-and-on screen persona were profitably played off against each other, this culminating in her Oscar-winning performance in Mike Nichols's *Who's Afraid of Virginia Woolf!* (1966). Directors like George Stevens and Joseph Losey spoke glowingly of her skill as a screen actress, but it was as a star that she excelled, and nobody symbolised celluloid glamour more seductively. From being its loveliest child star, Elizabeth Taylor came to be fairly regarded as Hollywood's Queen Mother.

Other important films: *Father of the Bride* (1950), *A Place in the Sun* (1951), *Butterfield 8* (1960), *Cleopatra* (1963), *Reflections in a Golden Eye* (1967) and *Secret Ceremony* (1968).

Temple, Shirley (1928–2014)

The most famous of all child stars, precociously talented at singing, dancing and emoting. The top box-office attraction of 1938, she was a has-been by 1940, and spent her adult life engaged not in movies but in Republican politics. Main films include: *Little Miss Marker* (1934), *Wee Willie Winkie* (1937) and *Rebecca of Sunnybrook Farm* (1938).

Tracy, Spencer (1900–67)

Tracy successfully embodied in the thirties and forties certain "all-American" qualities—bluff decency, perceptive kind-heartedness, the "Honest Joe" syndrome—marked in such movies as Fritz Lang's *Fury* (1936) and Frank Borzage's *Big City* (1937). With Katharine Hepburn, he formed one of the archetypal American-movie couples. They strike sparks off each other in *Adam's Rib* and *Pat and Mike* for George Cukor (1949 and 1952 respectively), and in work for such directors as George Stevens and Frank Capra. An actor's actor, so natural that he seemed not to be acting at all, he was greatly admired by his peers, not least by Laurence Olivier, who commented: "I've learned more about acting from watching Tracy than in any other way. He has great truth in eveything he does."

His key films included: *San Francisco* (1936), *Captains Courageous* (1937), *Boys' Town* (1938), *Woman of the Year* (1942), *Father of the Bride* (1950), *The Actress* (1953), *Bad Day at Black Rock* (1955), *Inherit the Wind* (1960) and *Judgment at Nuremberg* (1961).

Valentino, Rudolph (1895–1926)

Valentino was one of the first major Hollywood sex symbols whose funeral after a premature death from peritonitis was followed by thousands of sobbing fans. This now seems ironic due not only to changes in film fashions and sexual coding that make his savagely passionate oriental in *The Sheik* (George Melford, 1921) appear passé, but also to subsequent revelations about his unconsummated first marriage, homosexual tendencies and domination by his second wife, who took charge of his career and mismanaged it abominably. To women he symbolised exotic eroticism; to men, to quote an infamous *Chicago Tribune* editorial, a "painted pansy".

His premature death (which is often a smart career move, as one cynical journalist remarked) only fanned the legend and the controversy. Other important films: *The Four Horsemen of the Apocalypse* (1921), *Blood and Sand* (1922) and *Son of the Sheik* (1926).

Wayne, John (1907–79)

Wayne remains perhaps Hollywood's greatest, most loved and most hated star. Loved, by Western fans the world over for performances that set the mould for the horseback hero—big physically and spiritually, charismatically dominating with men, awkward and latently sentimental with women, always coming out on top in a crisis. Hated, for his uncompromising right-wing political stance which led him to endorse the McCarthyite persecutions of the fifties and to give active support to the American invasion of Vietnam, even making a film—*The Green Berets* (1968)— in support of it. As an actor, Wayne revealed in his best parts more sensitivity than he often cared to off-screen—as the outlaw Ringo in Ford's *Stagecoach* (1939) who ends up with the prostitute Dallas, as the tamed Comanche-hater Ethan Edwards in Ford's *The Searchers* (1956), who walks off into the barren landscape at the end, and as the sheriff in Hawks's *Rio Bravo* (1959), holding a motley posse together by force of personality. He won an Oscar for *True Grit* (1969). Other important films: *Fort Apache* (1948), *Red River* (1949), *She Wore a Yellow Ribbon* (1949), *Sands of Iwo Jima* (1950), *The Quiet Man* (1952), *The Man Who Shot Liberty Valance* (1962) and *The Shootist* (1976).

West, Mae (1892–1980)

"I was Snow White—but I drifted." So said Mae West, whose raunchy style was seen at its best on film in *She Done Him Wrong* (1933) and *I'm No Angel* (1933). This blousy buxom blonde appealed to men because of her sex-appeal, and to women because of the way she seized the sexual initiative from the male and sent up his desires. Unfortunately the production code of 1934, which laid down strict guidelines on the treatment of sex on film, inhibited Miss West's screen career. Other key films include: *Belle of the Nineties* (1934) and *My Little Chickadee* (1940).

4. GLOSSARY OF FILM TERMS

Art director, technician responsible for the designing of the sets

Art-house film, a film commonly thought by critics to have artistic merit and often shown at specialist rather than mainstream cinemas.

Auteur, literally French for 'author', but generally a complimentary term bestowed by critics on a director whose films are deemed to exhibit stylistic and thematic distinctiveness and distinction. The so-called 'auteur theory', popularised in France in the 1950s, ascribed overall responsibility for the creation and quality of a film to its director, thereby renewing critical analysis of much previously neglected Hollywood work. The *'politique des auteurs'* (policy of authors) was first stated by François Truffaut in the January 1954 issue of *Cahiers du Cinema*; the main exponent of the auteur theory in America was the critic Andrew Sarris.

Back lighting, lighting directed at the camera from behind the subject, which is therefore silhouetted.

Back projection, background scene projected onto a screen behind the action to give the impression the actors are on a real location. A convention of classic Hollywood cinema that can now look dated, it became a source of keen critical debate in Hitchcock's *Marnie* (1964), where its perceptible use was both attacked for technical sloppiness and defended as expressively appropriate and meaningful.

Best boy, the main assistant to a film's chief electrician.

Bio-pic, a film about the life of a real person. It was a kind of film particularly popularised by Warner Brothers in the 1930s *e.g. The Story of Louis Pasteur* (1936) and *The Life of Emile Zola* (1937). Writers, sportsmen, composers, scientists, painters have all come under the spotlight: recent real-life subjects whose life and work have inspired successful films range from Virginia Woolf and

Truman Capote to Mohammed Ali.

B-picture, generally a modest, low-budget production that, during the cinema's peak of popularity between 1930 and 1960, preceded the main feature. Often of low quality (one remembers the mortifying comment in the 1957 British comedy, *The Smallest Show on Earth*: 'She was as pretty as a picture- a B-picture, mind you'), B-pictures could sometimes prove to be useful training grounds for directors (*e.g.* Fred Zinnemann) who were to move on to bigger things, and some of the films were to become cult classics.

Camera angle, looking up, looking down, tilted (the latter used particularly strikingly in Carol Reed's 1949 classic, *The Third Man* to suggest a world out of joint).

Cannes Film Festival, the most glamorous of the annual international film festivals, generally taking place in May and whose top prize, the 'Golden Palm' gives its recipient valuable prestige and publicity.

CGI, or computer generated images, as seen to spectacular effect in such films as *Jurassic Park* (1993), *Toy Story* (1995), and *Gladiator* (2000). As George Lucas told Martin Scorsese during the shooting of his lavishly expensive *Gangs of New York* (2002): 'Sets like that can be done with computers now.'

Chiaroscuro, a striking or stylised use of light and shadow.

Cinemascope, a wide-screen process developed by Twentieth Century Fox and first used for their religious epic, *The Robe* (1953).

Cinema verité, literally 'cinema truth': it signified a kind of documentary cinema that used lightweight, hand-held equipment, minimal crews and interview techniques on real locations.

Crane shot, a shot where the camera is mounted on a crane and rises above the ground to offer an aerial perspective on the action. A famous example is the shot in Fred Zinnemann's *High Noon* (1952), where the crane shot of the Marshal in the empty street prior to his confrontation with the four outlaws emphasises his isolation, rejection and vulnerability.

Crosscutting, cutting back and forth from one action to another, giving the impression of parallel action and the events happening simultaneously or one event commenting on the other. Famous examples include the finale of D W Griffith's *Intolerance* (1916), where the chase to save the pardoned hero from execution in the modern story is crosscut with Christ's procession to Calvary; and the scene in Francis Ford Coppola's *The Godfather* (1972), where the baptism of Michael Corleone's godson is crosscut with the violent elimination of Corleone's Mafia rivals.

Cult movie, a film which gathers an underground reputation as a classic because of its appreciation by a specialist audience of followers, often in defiance of mainstream taste.

Cut, change from one shot to another. *See also* **Crosscutting** and **Match cut**.

Day for night, a technique used for shooting night sequences during daytime with the use of special lens filters. Alluded to in François Truffaut's film about film-making, *La Nuit Americaine—Day for Night* (1973)

Deep focus, a photographic technique in which objects far away from the camera as well as those in the foreground of the frame are in focus at the same time. It was particularly associated with the cameraman Gregg Toland and his work on the 1940s films of Orson Welles (*Citizen Kane*) and William Wyler (*The Little Foxes, The Best Years of our Lives*). It was considered to be an enhancement of film realism by the influential French film theorist, André Bazin.

Director's cut, a re-edited version of a classic film that supposedly restores, or more closely represents, the director's original intentions. Examples include David Lean's *Lawrence of Arabia*, Sam Peckinpah's *Pat Garrett and Billy the Kid* and Ridley Scott's *Blade Runner*.

Dissolve, a visible transition where one shot fades out as another fades in. A powerful example occurs in Hitchcock's *The Wrong Man* (1957), where Hitchcock slowly dissolves from a shot of unjustly accused Henry Fonda as he prays for help to that of the actual criminal about to attempt a robbery that will clear Fonda's name.

Documentary, a term first coined by John Grierson when describing Robert Flaherty's film about the daily life of a Polynesian youth, *Moana* (1926). It derived from the French word *documentaire*, which the French used to describe travelogues, but it has come to be applied to all non-fiction films that show real events and people, albeit covering a wide variety of styles.

Dogme 95, a manifesto by key Danish film-makers such as Lars von Trier and Thomas Vinterberg, which eschewed the cinema of spectacle and special effects and lauded the 'inspiration of limitation' (natural sound, location shooting, hand-held camerawork *etc.*) An antithesis to the *Titanic* kind of cinema, its practice was short-lived—seen at its best in Vinterberg's *Festen* (1995) and its most controversial in von Trier's *The Idiots* (1998)—but, as the British director Michael Winterbottom commented, 'it was attractive as a polemic or provocation.'

Ealing comedy, a series of British comedies made at Ealing studios in West London that poked fun at bureaucracy, officialdom and the quaintness of British character. Its heyday was between 1949 and 1955, framed by the two darkest and most subversive achievements of the genre, Robert Hamer's *Kind Hearts and Coronets* and Alexander Mackendrick's *The Ladykillers*.

Establishing shot, opening shot of a scene that establishes the location or setting.

Fade in/Fade out, an optical device whereby the image appears/disappears gradually.

Film noir, films with a grim urban setting that deal mainly with dark and violent passions (often triggered by a seductive *femme fatale*) in a downbeat way. The term was applied by French critics to American thrillers of the 1940s, particularly those directed by European émigrés like Billy Wilder (*Double Indemnity*), Robert Siodmak (*The Killers*) and Fritz Lang (*Woman in the Window, Scarlet Street)*, who intensified their themes with distorted imagery and stylised use of lighting and shadow that also owed something to German Expressionism (*see below*).

Fish-eye lens, a lens with such a wide angle that it distorts the image: used particularly effectively by cameraman James Wong Howe in John Frankenheimer's *Seconds* (1966) to enhance the horror of Rock Hudson's final journey to the operating table.

Flashback, scene or shot that disrupts the chronological narrative of a film to show events that happened in the past or before the main story began.

Flashforward, scene or shot that interrupts the chronological flow of a narrative to show future events.

Free cinema, a documentary movement in England in the 1950s that was a precursor of the British New Wave films of the early 1960s and was a springboard for the careers in film of directors such as Lindsay Anderson, Karel Reisz and Tony Richardson, who wished to bring a grittier honesty and realism to their portrait of English society.

Freeze frame, a shot where the action is 'frozen' into stillness, as in the famous endings of François Truffaut's *Les Quatre Cents Coups* (1959), George Roy Hill's *Butch Cassidy and the Sundance Kid* (1969), and Ridley Scott's *Thelma and Louise* (1992).

Gaffer, the chief electrician on a production.

Genre, a type or class of film (*e.g.* the musical, the western).

German expressionism, a style of film common in Germany in the twenties, typified by dramatic lighting, distorted sets, symbolic action and characterisation, as in, for example, Robert Wiene's *The Cabinet of Dr Caligari* (1919).

Hammer horror, English horror films from Hammer studios which made stars of regulars such as Peter Cushing and Sir Christopher Lee and cult figures of directors such as Terence Fisher.

Hays Office, essentially the body that regulated what constituted good taste and acceptable behaviour on screen during the heyday of Hollywood. It was run by a former lawyer and conservative politician, Will Hays, and was the creation of the studio moguls in 1930, designed to improve the image of Hollywood after a series of highly publicised scandals about 'immoral' behaviour. The so-called Hays Code had an enormous influence on the content of Hollywood films until its termination in 1966.

Hollywood Ten, the ten artists who were imprisoned for contempt of Congress in 1948 when they refused to disclose their political affiliations to the

House UnAmerican Activities Committee (HUAC) during its infamous investigation into so-called 'Communist infiltration into the Hollywood motion picture industry'. The investigation provoked a climate of fear and period of blacklisting that permanently scarred the film community.

The ten individuals were producer-director Herbert Biberman, director Edward Dmytryk, producer-writer Adrian Scott, and writers Alvah Bessie, Lester Cole, Ring Lardner Jr., John Howard Lawson, Albert Maltz, Samuel Ornitz and Dalton Trumbo.

Kuleshov experiment, a montage experiment by the early Soviet director, Lev Kuleshov, which juxtaposed shots of the actor, Ivan Mozhukin with different objects to generate different meanings—*i.e.* the same expression of the actor juxtaposed with a shot of a child, a plate of soup, a coffin, was read by audiences to express tenderness, hunger and grief, respectively. In other words, the meaning was not in the shot itself but in the combination of images, showing the power of editing to alter perception. Subsequent film theorists have cast doubt on the claims and even existence of this experiment, but it did influence attitudes to the cinema and montage. Hitchcock's *Rear Window* (1954) could be said to derive its whole editing style from this 'experiment'.

MacGuffin, a term associated with Alfred Hitchcock and applied to a plot device that is of little interest in itself but is there simply to generate the action (like the microfilm that James Mason is trying to smuggle out of the country in *North by Northwest*).

Match cut, two shots linked by some aural or visual connection, like the moment in Stanley Kubrick's *2001:A Space Odyssey* (1968), where a bone tossed in the air by a primordial ape is visually displaced by the shot of a spinning spacecraft; or the moment in Nicolas Roeg's *Don't Look Now* (1973), where the director cuts from the wife's scream on seeing her dead daughter to the drill her husband is using in his reconstruction work on the church in Venice, a sound match and cut that, as Roeg said, fires the viewer like a bullet into the future.

Method acting, a style of acting influenced by the teachings of Konstantine Stanislavsky (1863-1938), which aimed to increase the realism of a performance by encouraging the actor to draw on his or her personal experiences to 'become' the character. Closely associated with the Actors' Studio in New York, it came to public attention in the 1950s through the striking and influential performances of actors such as Marlon Brando, James Dean and Paul Newman.

Mise-en-scene, literally, 'staging'—the way in which the elements and components in a film are arranged and encompassed by the camera, or the term normally used to denote that part of the cinematic process that takes place on the set, as opposed to montage, which takes place afterwards.

Montage, the juxtaposition of material (successive shots, or items within a shot) to suggest meaning—as when Eisenstein in *Battleship Potemkin* (1925) evokes anger at the massacre on the Odessa Steps by showing three successive shots of stone lions in various positions, shot to look as though they are one lion rising to its feet and roaring its fury. Or simply another word for a film's editing.

Movie brats, a new generation of Hollywood directors, many of them from film school, who exploded onto the scene in the early 1970s—(*e.g.* George Lucas, Brian DePalma, Martin Scorsese, Steven Spielberg).

Narration, the various means by which the events of the plot can be placed before the viewer. Also used of voice-over narration, a technique particularly associated with the fatalism of film noir, like that of the mortally wounded hero in *Double Indemnity* (1944) as he confesses his crime into a dictaphone, or that of the writer in *Sunset Boulevard* (1950), who, lying dead at the bottom of a movie star's swimming pool, reflects on how he got there.

Narrative, structured series of events, linked by cause and effect, that provides the film's plot.

Nickelodeon, a makeshift movie theatre in the early days of cinema, so called because the admission price was only a nickel.

Neo-realism, connected with movement out of the studio, shooting on real locations, absence of a script and/or non-professional casts, all designed simultaneously to cut costs and increase the impression of spontaneity and real life. Inaugurated by Renoir but particularly associated with Italian directors of the immediate post-war period (Rossellini, Visconti, DeSica), who rejected the escapism of the national cinema to make films that reflected contemporary social conditions.

Nouvelle Vague, a term for a loose heterogeneous group of young French film critics (including Chabrol, Godard and Truffaut), who went into direction in the late 1950s and early 1960s and created an enormous impact with their experimental style and their laconic sense of existential amorality.

Pan, a shot where the camera looks around from a stationary position. It can be used for dramatic effect, as in John Ford's *Stagecoach* (1939), when a brief panning shot reveals the presence of an Indian war party just when the stagecoach seems to be heading for safety; or, more elaborately, in John Frankenheimer's *The Manchurian Candidate* (1962), where a 360-degree panning shot introduces the film's famous brainwashing sequence.

Point of view shot, a shot where the action is seen through the eyes of a particular character, the shot generally preceded or followed by the shot of the character looking. Used with particular effectiveness by Hitchcock in films such as *Rear Window* and *Vertigo* (1958). Robert Montgomery's *Lady in the Lake* (1948) also experimented with a subjective camera by showing us only what the leading character saw and only showing the character himself in mirror shots.

Romcom. Romantic comedy.

Screwball comedy, a type of comedy particularly popularised by directors like Howard Hawks and Preston Sturges in the 1930s and early 1940s and characterised by frantic action, rapier wit, and a couple in a bizarre situation. Fine examples would include: Capra's *It Happened One Night* (1934), Hawks's *Bringing Up Baby* (1938) and Sturges' *Palm Beach Story* (1942).

Silent period, roughly that period of film history between the Lumières in 1895 and *The Jazz Singer* in 1927, when most films were shot without sound, although, when exhibited, were often supported by sound effects and live piano accompaniment.

Sleeper, a term used of a film which initially escapes attention but gradually acquires a following, either cult or commercial.

Sneak preview, a tryout of a film to gauge audience reaction. In some notorious cases, such as Orson Welles's *The Magnificent Ambersons* (1942) and John Huston's *The Red Badge of Courage* (1951), the disastrous preview response caused the studios to panic and butcher the films through desperate re-editing.

Spaghetti western, a western made in Italy by Italian film-makers, which commonly stylises the action and often parodies genre conventions. The genre became particularly popular in the 1960s because of the successful association on the 'Dollars' films of actor Clint Eastwood and director Sergio Leone.

Storyboard, series of sketches of the shots that comprise a scene and a useful reference for a director when shooting particularly complicated pieces of action.

Ten-minute take, a ten-minute sequence filmed in a single take without cuts. Particularly associated with Alfred Hitchcock and his deployment of the technique in *Rope* (1948) and *Under Capricorn* (1949).

Tracking shot, camera moves forward or backwards in order to follow subject, a technique taken to an extreme in the elaborate three-minute continuous shot that opens Orson Welles's *Touch of Evil* (1958) and to which Robert Altman pays homage in *The Player* (1992).

Zoom shot, a shot during which the focal length of the lens is adjusted and gives the impression of optical motion without moving the camera backwards or forwards. The zoom lens has been used to particularly expressive effect by directors such as Robert Altman and Stanley Kubrick.

5. THE OSCAR WINNERS

Introduction

The film industry's most glittering prize remains the Hollywood Academy Award, or "Oscar'. The "Oscar' came about as a result of the formation of the Academy of Motion Picture Arts and Sciences in 1927. The Academy thought it would gain additional prestige and publicity if it gave out annual awards for artistic and technical merit. The first awards ceremony was in May 1929 and was a modest affair.

The Statuette

The Oscar itself is a gold-plated statuette of a knight holding a crusader's sword and standing on a reel of film whose five spokes symbolise the original branches of the Academy (actors, directors, producers, technicians and writers). Legend has it that the name comes from a secretary Margaret Herrick, later an executive director of the Academy, who commented one day that the statuette "reminds me of my uncle Oscar". The first documented use of the nickname Oscar was in 1934.

Oscar Records

Ben-Hur (1959), *Titanic* (1997) and *Lord of the Rings: Return of the King* (2003) hold the record number of Oscars—11. *West Side Story* (1961) won 10; *Gone With the Wind* (1939), *Gigi* (1958), *The Last Emperor* (1987) and *The English Patient* (1996) each won nine.

Katharine Hepburn has won more major acting Oscars than any other star (4). Bette Davis, Luise Rainer, Olivia de Havilland, Ingrid Bergman, Glenda Jackson, Jane Fonda, Sally Field, Elizabeth Taylor, Jodie Foster and Hilary Swank have won Best Actress twice; Sir Daniel Day-Lewis has won Best Actor a record three times. Other actors to have won twice are Spencer Tracy, Fredric March, Gary Cooper, Marlon Brando, Dustin Hoffman, Jack Nicholson, Tom Hanks, and Sean Penn.

Best Actor

1927–28	Emil Jannings, *The Way of All Flesh*
1928–29	Warner Baxter, *In Old Arizona*
1929–30	George Arliss, *Disraeli*
1930–31	Lionel Barrymore, *A Free Soul*
1931–32	Fredric March, *Dr Jekyll and Mr Hyde*; Wallace Beery, *The Champ* (tie)
1932–33	Charles Laughton, *Private Life of Henry VIII*
1934	Clark Gable, *It Happened One Night*
1935	Victor McLaglen, *The Informer*
1936	Paul Muni, *Story of Louis Pasteur*
1937	Spencer Tracy, *Captains Courageous*
1938	Spencer Tracy, *Boys Town*
1939	Robert Donat, *Goodbye Mr Chips*
1940	James Stewart, *The Philadelphia Story*
1941	Gary Cooper, *Sergeant York*
1942	James Cagney, *Yankee Doodle Dandy*
1943	Paul Lukas, *Watch on the Rhine*
1944	Bing Crosby, *Going My Way*
1945	Ray Milland, *The Lost Weekend*
1946	Fredric March, *The Best Years of Our Lives*
1947	Ronald Colman, *A Double Life*
1948	Laurence Olivier, *Hamlet*
1949	Broderick Crawford, *All the King's Men*
1950	José Ferrer, *Cyrano de Bergerac*
1951	Humphrey Bogart, *The African Queen*
1952	Gary Cooper, *High Noon*
1953	William Holden, *Stalag 17*
1954	Marlon Brando, *On the Waterfront*
1955	Ernest Borgnine, *Marty*
1956	Yul Brynner, *The King and I*
1957	Alec Guinness, *The Bridge on the River Kwai*
1958	David Niven, *Separate Tables*
1959	Charlton Heston, *Ben-Hur*
1960	Burt Lancaster, *Elmer Gantry*
1961	Maximilian Schell, *Judgment at Nuremberg*
1962	Gregory Peck, *To Kill a Mockingbird*
1963	Sidney Poitier, *Lilies of the Field*
1964	Rex Harrison, *My Fair Lady*
1965	Lee Marvin, *Cat Ballou*
1966	Paul Scofield, *A Man for All Seasons*
1967	Rod Steiger, *In the Heat of the Night*
1968	Cliff Robertson, *Charly*
1969	John Wayne, *True Grit*
1970	George C. Scott, *Patton* (refused)
1971	Gene Hackman, *The French Connection*
1972	Marlon Brando, *The Godfather* (refused)
1973	Jack Lemmon, *Save the Tiger*
1974	Art Carney, *Harry and Tonto*
1975	Jack Nicholson, *One Flew Over the Cuckoo's Nest*
1976	Peter Finch, *Network*
1977	Richard Dreyfuss, *The Goodbye Girl*
1978	Jon Voight, *Coming Home*
1979	Dustin Hoffman, *Kramer vs. Kramer*
1980	Robert DeNiro, *Raging Bull*
1981	Henry Fonda, *On Golden Pond*
1982	Ben Kingsley, *Gandhi*
1983	Robert Duvall, *Tender Mercies*
1984	F. Murray Abraham, *Amadeus*
1985	William Hurt, *Kiss of the Spider Woman*
1986	Paul Newman, *The Color of Money*
1987	Michael Douglas, *Wall Street*
1988	Dustin Hoffman, *Rain Man*
1989	Daniel Day-Lewis, *My Left Foot*
1990	Jeremy Irons, *Reversal of Fortune*
1991	Anthony Hopkins, *The Silence of the Lambs*
1992	Al Pacino, *Scent of a Woman*
1993	Tom Hanks, *Philadelphia*
1994	Tom Hanks, *Forrest Gump*
1995	Nicolas Cage, *Leaving Las Vegas*
1996	Geoffrey Rush, *Shine*
1997	Jack Nicholson, *As Good As It Gets*
1998	Roberto Benigni, *Life is Beautiful*
1999	Kevin Spacey, *American Beauty*
2000	Russell Crowe, *Gladiator*
2001	Denzel Washington, *Training Day*
2002	Adrien Brody, *The Pianist*
2003	Sean Penn, *Mystic River*
2004	Jamie Foxx, *Ray*
2005	Philip Seymour Hoffman, *Capote*
2006	Forest Whitaker, *The Last King of Scotland*
2007	Daniel Day-Lewis, *There Will Be Blood*
2008	Sean Penn, *Milk*
2009	Jeff Bridges, *Crazy Heart*
2010	Colin Firth, *The King's Speech*
2011	Jean Dujardin, *The Artist*
2012	Daniel Day-Lewis, *Lincoln*
2013	Matthew McConaughey, *Dallas Buyers Club*
2014	Eddie Redmayne, *The Theory of Everything*
2015	Leonardo DiCaprio, *The Revenant*
2016	Casey Affleck, *Manchester by the Sea*

Best Actress

1927–28	Janet Gaynor, *Seventh Heaven*
1928–29	Mary Pickford, *Coquette*
1929–30	Norma Shearer, *The Divorcee*
1930–31	Marie Dressler, *Min and Bill*
1931–32	Helen Hayes, *Sin of Madelon Claudet*
1932–33	Katharine Hepburn, *Morning Glory*
1934	Claudette Colbert, *It Happened One Night*
1935	Bette Davis, *Dangerous*
1936	Luise Rainer, *The Great Ziegfeld*
1937	Luise Rainer, *The Good Earth*
1938	Bette Davis, *Jezebel*
1939	Vivien Leigh, *Gone With the Wind*
1940	Ginger Rogers, *Kitty Foyle*
1941	Joan Fontaine, *Suspicion*
1942	Greer Garson, *Mrs Miniver*
1943	Jennifer Jones, *The Song of Bernadette*
1944	Ingrid Bergman, *Gaslight*
1945	Joan Crawford, *Mildred Pierce*
1946	Olivia de Havilland, *To Each His Own*
1947	Loretta Young, *The Farmer's Daughter*
1948	Jane Wyman, *Johnny Belinda*
1949	Olivia de Havilland, *The Heiress*
1950	Judy Holliday, *Born Yesterday*
1951	Vivien Leigh, *A Streetcar Named Desire*
1952	Shirley Booth, *Come Back, Little Sheba*
1953	Audrey Hepburn, *Roman Holiday*
1954	Grace Kelly, *Country Girl*
1955	Anna Magnani, *The Rose Tattoo*
1956	Ingrid Bergman, *Anastasia*
1957	Joanne Woodward, *The Three Faces of Eve*
1958	Susan Hayward, *I Want to Live*

1959	Simone Signoret, *Room at the Top*
1960	Elizabeth Taylor, *Butterfield 8*
1961	Sophia Loren, *Two Women*
1962	Anne Bancroft, *The Miracle Worker*
1963	Patricia Neal, *Hud*
1964	Julie Andrews, *Mary Poppins*
1965	Julie Christie, *Darling*
1966	Elizabeth Taylor, *Who's Afraid of Virginia Woolf?*
1967	Katharine Hepburn, *Guess Who's Coming to Dinner*
1968	Katharine Hepburn, *The Lion in Winter*; Barbra Streisand, *Funny Girl* (tie)
1969	Maggie Smith, *The Prime of Miss Jean Brodie*
1970	Glenda Jackson, *Women in Love*
1971	Jane Fonda, *Klute*
1972	Liza Minnelli, *Cabaret*
1973	Glenda Jackson, *A Touch of Class*
1974	Ellen Burstyn, *Alice Doesn't Live Here Anymore*
1975	Louise Fletcher, *One Flew Over the Cuckoo's Nest*
1976	Faye Dunaway, *Network*
1977	Diane Keaton, *Annie Hall*
1978	Jane Fonda, *Coming Home*
1979	Sally Field, *Norma Rae*
1980	Sissy Spacek, *Coal Miner's Daughter*
1981	Katharine Hepburn, *On Golden Pond*
1982	Meryl Streep, *Sophie's Choice*
1983	Shirley MacLaine, *Terms of Endearment*
1984	Sally Field, *Places in the Heart*
1985	Geraldine Page, *The Trip to Bountiful*
1986	Marlee Matlin, *Children of a Lesser God*
1987	Cher, *Moonstruck*
1988	Jodie Foster, *The Accused*
1989	Jessica Tandy, *Driving Miss Daisy*
1990	Kathy Bates, *Misery*
1991	Jodie Foster, *The Silence of the Lambs*
1992	Emma Thompson, *Howards End*
1993	Holly Hunter, *The Piano*
1994	Jessica Lange, *Blue Sky*
1995	Susan Sarandon, *Dead Man Walking*
1996	Frances McDormand, *Fargo*
1997	Helen Hunt, *As Good As It Gets*
1998	Gwyneth Paltrow, *Shakespeare in Love*
1999	Hilary Swank, *Boys Don't Cry*
2000	Julia Roberts, *Erin Brockovich*
2001	Halle Berry, *Monster's Ball*
2002	Nicole Kidman, *The Hours*
2003	Charlize Theron, *Monster*
2004	Hilary Swank, *Million Dollar Baby*
2005	Reese Witherspoon, *Walk the Line*
2006	Helen Mirren, *The Queen*
2007	Marion Cotillard, *La Vie en Rose*
2008	Kate Winslet, *The Reader*
2009	Sandra Bullock, *The Blind Side*
2010	Natalie Portman, *Black Swan*
2011	Meryl Streep, *The Iron Lady*
2012	Jennifer Lawrence, *Silver Linings Playbook*
2013	Cate Blanchett, *Blue Jasmine*
2014	Julianne Moore, *Still Alice*

FOOD AND DRINK

I. THE WORLD OF WINE

INTRODUCTION.

Wine is simply an alcoholic beverage made by fermenting the sugars in grape juice, making alcohol. This simple definition belies the multifarious variables, both natural and man-made which affect the final taste. Different soils, grape varieties and climates, the decisions made by the grape farmer and the wine maker, and the vagaries of the weather mean that there is infinite variety in wine. This choice is what makes wine so fascinating. It is, however, too easy to forget that wine is, for many, one of the staples of life; as much part of the daily routine as bread. As such it is a simple and healthy beverage, something to be talked over, not talked about.

Most of the world's wine is produced in Europe. Italy and France are the biggest producers, followed by Spain. Wine consumption is similarly concentrated in the producing countries, with France, for example consuming over 60 litres per capita, compared with a quarter of this in the UK. Consumption is declining in the major producing countries, but increasing in many countries like the United Kingdom where production is limited. Meanwhile China is now the world's second-largest grower by area under cultivation (after Spain).

History.

It is probable that the first wine was accidental. Perhaps wild grapes were left too long in a pot after being gathered. The weight of the grapes would cause those at the bottom to split, releasing juice which will ferment spontaneously as the necessary yeasts exist naturally on the grapes. The first recorded vineyard in the Judaic and Christian world appears in Genesis. Once the Ark landed after the great flood, Noah planted a vineyard, presumably on the slopes of Mount Ararat. Archaeological evidence too points to south-eastern Europe or the Middle East being wine's original home. Some of today's grape varieties bear witness to the middle eastern connection – the Syrah or Shiraz grape, originally from Syria, and the Muscat.

Wine was certainly known in ancient Egypt and Greece but it was Rome that spread viticulture far and wide. The histories of many of Europe's vineyard regions, from the Rhône to England start with "the vine was originally brought by the Romans". In only a few areas, such as Jerez in Southern Spain, were the Phoenicians responsible. Beyond Europe and the Mediterranean, the wine grape travelled with the European discoverers. Portuguese navigators and Spanish conquistadors were Catholics; they needed wine for the sacrament. Vineyards were established in South America in the 16th century, later spreading into California and the rest of North America. The Cape of Good Hope, established as a victualling station for the Dutch East India Company, was planted with fruit including vines, and the first grapes were pressed in 1652.

Australasian vineyards were first planted with cuttings from the Cape.

The Taste of Wine.

A number of different factors influence the taste of wine. Climate, weather and soil are natural. Man can only make minor adjustments to this. The decision as to which grape variety to plant is that of the grower, but it is influenced heavily by the climate. Some grapes, such as Riesling, excel in cold areas, others can resist drought and excessive heat. Human influence is most important in grape growing (viticulture) and wine making (vinification) as at each stage of these processes decisions have to be made which will influence its character and quality.

Climate.

Since wine is made from grapes, it follows that it can be made anywhere that grapes can be made to ripen, from as far north as Britain to as far south as New Zealand. In practice there are two bands, one each side of the equator, within which the wine vine, *Vitis vinifera* produces well, situated approximately within the latitudes of 30° to 50° north and south of the equator. Within these zones the climate is suitable for vine cultivation. Other areas are either too cold for the grapes to ripen, or too warm, so the vine turns its energies to vegetative growth rather than fruit production. These bands cover large climatic variations. In the northern hemisphere the band stretches from Germany and southern Britain to North Africa. In the cooler climates, those nearer to the poles, the grapes are only just ripe and produce lighter wines, often with crisp, refreshing acidity. Most of these are white wines. The warmer climatic zones produce riper grapes with higher sugar content and lower acidity. This translates into higher alcohol and lower acidity in the wines, and the wines tend to have more body.

The black grapes needed for red wine need more sun, so these areas produce more red wine.

Climate is affected by other geographical features such as proximity to or distance from large bodies of water, ocean currents, altitude and topography. Neighbouring vineyards can produce very different wines, particularly in the more marginal areas. In the Mosel in Germany the best wines are planted on steep south-facing slopes overlooking the river. The next plot of land, perhaps just around the next bend in the river, might be more shaded, to the detriment of the wines.

Weather.

A region's climate is separate and distinct from its weather. The climate is a function of the geography. The topography and latitude do not vary, whereas weather patterns can alter from one year to the next. This is why one hears about good or bad vintages; a cold night in spring, or rain at the wrong time can adversely affect the crop. Annual weather conditions, sometimes philosophically referred to as the luck of the year, have more influence on wines from the traditional areas of western Europe, where the weather is variable, than "newer" areas such as Australia where the weather is more stable.

Soil.

Soil can have a profound influence on the taste of a wine, as can be seen from the subtle difference between wines from neighbouring vineyards. Vines assimilate trace elements through their roots which alter the chemical composition of the wine. The role of the soil is, however, generally more prosaic. Vines need good drainage, so chalk in Champagne and gravel in the Médoc are ideal. Other hotter areas, like the Sherry region in Spain, rely on the absorbent subsoil to retain water for the vine in the dry summers. Many vineyards are planted in soil which could not support any other agriculture because vines can stand poor soil.

Grape Variety.

As with other fruit, different grape varieties have different flavours, which show in the finished wine. Thousands of different grape varieties are used in wine production. Most are undistinguished, found only in certain areas where they make indifferent wine. However, other varieties have distinctive, recognizable flavours. These more noble grapes are often used unblended, sold under the varietal name. Grapes like Cabernet Sauvignon, Pinot Noir and Chardonnay have become popular internationally. They often flourish in their new homes to the extent that they have become better known there than in the original regions. New Zealand has adopted Sauvignon Blanc, and Australia Shiraz, developing their own particular and highly successful styles.

Grape Growing (Viticulture).

The vine needs careful tending if viticulture is to be profitable. Vines grow prolifically during the spring and summer, so in the winter they are severely pruned. A hedge of vines six or seven feet tall will be reduced to a series of small canes, or short spurs, as the pruners remove the dormant wood. Pruning not only allows access for other vineyard operations, it can also be used to control the quantity and quality of the fruit. Received wisdom is that these are inversely related, so a grower aiming for a high quality wine will prune even more severely to reduce the yield, whereas a bulk producer will maximize it. The main task for the viticulturalist during the rest of the year is controlling the pests and diseases that can attack the vine. Control of fungal and viral infection, and protection from birds and small animals and insect pests is vital. The most serious vineyard pest is *Phylloxera vastarix*, the vine louse accidentally imported to Europe from America during the 19th century. It devastated European vineyards, almost wiping out production until it was discovered that vines grafted onto rootstocks of American native vines were tolerant to it. Since then virtually all European vines have had to be grafted.

Once ripe, the grapes will be harvested, either by hand or machine, and taken to the winery to be made into wine.

Wine Making (Vinification).

Ripe grapes contain all the components required to make wine. The grape consists of a soft pulp gorged with sugar, water and acids, contained in a thin skin which contains colouring, additional flavouring matter and tannins. Tannins are an important preservative in red wines. On the surface of the grape there is a waxy bloom of yeast, required for fermentation. Wine making is thus a natural process; the wine maker's job is to control this.

White Wine Production.

White wine can be made from black or white grapes as all the colouring matter in black grapes is in the skins. The grapes will be pressed and the resulting clear juice (called *must*) transferred to a fermenting vessel where yeasts, either natural or added, convert the sugar into alcohol. For white wine the fermenters are usually kept cool to maintain the aromatic characters. After fermentation the young wine will be clarified and allowed to mature. Most white wines are matured for a short time only, some spending time in oak barrels to add flavour and complexity.

Many white wines are dry, *i.e.* with no detectable sweetness, but there are a number of medium-dry and sweet white wines. To make inexpensive medium-dry wines a quantity of unfermented sterile grape juice is added to the wine just before bottling. High quality classic dessert wines, Sauternes, Tokaji *etc.*, are made with grapes in which the sugars have been concentrated by the action of a fungus called *Botrytis cinerea*. This shrivels the grapes so they look like mouldy raisins. They may look unappealing, but the wines are stunning. It is also possible to make a sweet wine by removing the yeasts physically by using a filter. This method is used in the production of wines such as Asti.

Red and Rosé Wine Production.

Black grapes are needed here. They are crushed, to break the skins and release the must, but fermented in contact with skins. As the alcohol is formed it extracts some of the colour and tannin, aided by stirring the wines up with pumps or paddles. For rosé wine the still fermenting must will be drained off after a day or two, when it has acquired some, but not much, colour. Red wines spend between five and fourteen days in contact with the skins, depending on the style required. Maturation will follow. For wines like Beaujolais this might only be a few weeks in large inert vats.

Other wines, such as fine Claret or Rioja might spend many months in oak barrels, followed by years, or even decades, in bottle, before reaching their peak.

Reading the Label.

A wine label is an advertisement, but also an identity card, giving all manner of information about the contents. It is a passport, permitting the wine to leave the producer's cellar and even reflects the character of the wine maker. Within the European Union (EU) wine legislation has codified regional, national and supranational regulations. Labels, like the wines themselves, must adhere to a host of rules, most of which consumers can ignore. Outside the EU the rules are less strict, but producers hoping to export must prove the integrity of their labels.

Wine Quality Grades.

All wine produced in the EU is officially categorised as either "Table Wine" or "Quality Wine". Table wine is required to reach certain minimum standards only, whereas quality wine which must come from a stated region must be made according to local regulations and should be typical of the area in which the grapes were grown. The use of the word "Quality" is potentially confusing. Quality wine must exhibit particular qualities, rather than necessarily being of intrinsically high quality. Quality wines are subject to controls on the area of production, type of grape varieties, minimum alcohol levels and methods of viticulture and vinification. Terms indicating Quality Wine include: *Vin Délimité de Qualité Supérieure* (VDQS) and *Appellation d'Origine Contrôlée* (AC) (France); *Qualitätswein bestimmte Anbaugebiete* (QbA) and *Qualitätswein mit Prädikat* (QmP) (Germany); *Denominazione di Origine Controllata* and *Denominazione di Origine Controllata e Garantita* (DOC and DOCG) (Italy); *Denominación de Origen* and *Denominación de Origen Calificada* (DO and DOC) (Spain) and *Denominação de Origem Controlada* in Portugal.

Category Changes.

Following revised labels, designed to make French wine more competitive globally, all French wines are now classed in one of three categories: *Vignobles de France* (Wines of France); *IGP* (*Indication Geographique Protegée* or Protected Geographical Region), which corresponds to existing *Vin de Pays*; and AOP (*Appellation d'Origine Protegée*) which tallies with the old AOC (*Appellation d'Origine Controlée*).

The labels now have the name of the grape and the year it was produced. Other changes mean any type of vine can be planted anywhere in France.

Table wines are usually labelled simply as table wine, but in the language of the producing country; *Vin de Table*, *Deutscher Tafelwein*, *Vinho de Mesa etc.* There is a higher grade of table wine which is usually well worth looking out for. These are the Country Wines, *Vins de Pays* in France, which often represent excellent value for money. Outside the EU, in particular in the New World, such rules do not apply. Here the producer's name is paramount and terms such as "Reserve", "Estate Wine", "Limited Release" *etc.* are used to denote the wines with the greatest character.

Other information on the label will include the country of origin, perhaps the region and maybe the grape variety. Each of these give some clue as to the taste of the wine. The year of vintage, when the grapes were picked and wine made, may also appear. This only indicates that all the wine in the bottle comes from the stated year. With the exception of Port and Champagne there is nothing inherently better about vintage wines; non-vintage wines can be as good.

WINES OF EUROPE.

FRANCE.

France has long been the United Kingdom's most important supplier of wines. We have been buying her wines since long before Eleanor of Aquitaine married Henri d'Anjou, thus bringing Bordeaux and England under the same crown.

Although the totals vary from year to year, around forty per cent of all wine consumed in the UK comes from France; nearly five bottles out of every case (12 bottles) sold. The range of prices and qualities from France is probably greater than anywhere else in the world, from the basic *Vin Rouge* to the finest Bordeaux and Burgundies selling for thousands of pounds a case in the auction rooms of London and New York.

The main wine producing regions are:

*Bordeaux
*Burgundy
*Alsace
*Loire Valley
*Rhône Valley
*Languedoc-Roussillon

Bordeaux.

For 300 years, after 1154, Bordeaux and England shared a monarch. Trade was further aided by the accessibility of the city of Bordeaux, on the Garonne, for ships from London and Bristol. In spite of subsequent political upheavals and Anglo-French wars, claret, the red wine of Bordeaux, remained a popular wine, keeping the smugglers busy when trade with France was proscribed.

Bordeaux is the largest fine wine producing region of France, accounting for about ten per cent of France's total wine production. The range includes some of the finest red and sweet white wines produced anywhere in the world, but the majority of wines called "Bordeaux" are simply everyday wines, best drunk young. The city that gives the region its name lies on the river Garonne. This large river joins the Dordogne to form the Gironde, a wide navigable estuary which eventually flows into the Bay of Biscay. The rivers, the Gironde and the proximity of the Atlantic Ocean give Bordeaux a maritime climate; mild and free of extremes, but humid which can be a problem for the viticulturalist.

This is an area of blended wines; only few varietal wines are sold. The red wines are made principally from Cabernet Sauvignon and Cabernet Franc, related varieties which give high tannin and acidity to the wine with Merlot, which produces higher alcohol, having a softer taste and less tannin. Generally the higher the Cabernet content, the longer the ageing required because of the tannin. Basic Bordeaux Rouge will have a high Merlot content so as to be easy to drink when young.

The two Bordeaux districts that use the highest proportion of Cabernet are the Médoc and Graves. The best wines need time to mature and soften, both in cask and bottle. The best known Merlot-dominated areas are St Emilion and Pomerol. The white wines are made predominantly from a blend of Sauvignon Blanc, an aromatic grape giving high acidity, and Sémillon, a thin skinned grape, easily attacked by noble rot, the basis of the sweet wines such as Sauternes.

Bordeaux is divided into several districts, those with the highest reputation are covered below.

Médoc AC.

The Médoc, the most famous of the Bordeaux districts, is divided into two. The Haut-Médoc, the southern part, being the better. Within the Haut Médoc are the famous communes, or parishes, of St Estèphe, Pauillac, St Julien and Margaux. The wines, which are all red, are usually sold under the names of the châteaux, or estate, where the grapes were grown. In 1855, to coincide with an exhibition in Paris, the best wines of Bordeaux were classified. All but one of the red wines come from the Haut-Médoc. The exception, Château Haut Brion, is from Graves. Hundreds of châteaux were eligible, yet a mere 62 were classified as *Cru classé* ("classed growths"), or vineyard. Five levels were identified, first to fifth growth. Originally only four châteaux, the greatest of all, were given the designation *premier cru* or first growth. Apart from the changes of ownership and occasional renaming of vineyards, the only change to the classification since its inception has been the promotion of Château Mouton Rothschild to First Growth in 1973.

Cru classé wines are thus inevitably expensive. *Cru Bourgeois*, a later classification, indicates above average, more affordable Bordeaux. Recent improvements have resulted in many of these having reached comparable quality to some *Cru Classé*.

Graves AC.

Graves is named for its gravel soil. Here red and white wines are produced, the latter in dry or off-dry styles. The northern part, around the city of Bordeaux, produces the best quality. Acknowledging this, the area was granted the AC Pessac-Léognan in 1987. Château Haut Brion is included in this appellation.

Sauternes AC.

Sauternes lies 30 miles south-east of Bordeaux, surrounded by Graves. Sauternes is always white and sweet, ideally made from grapes affected by *Botrytis cinerea*. The shrivelled grapes yield very concentrated juice which results in fine sweet wines. Like the Médoc, Sauternes was classified in 1855. Château d'Yquem became the only *Premier Grand Cru Classé*. There are also *Premier* and *Deuxième Cru Châteaux*.

Barsac is a commune within Sauternes. Its wines may be labelled Barsac or Sauternes, so all Barsac is Sauternes, but not all Sauternes is Barsac.

St Emilion AC.

On the right bank the soil is heavier, and the terrain hillier. The Merlot grown here gives wines rich in flavour, but which mature earlier than the wines of the Médoc. St Emilion is an Appellation for red wines only. Classification came later here, in 1955. In contrast to the Médoc it is revised every decade, so there is a variable number of classified Châteaux. The two most famous are Châteaux Ausone and Cheval Blanc.

Pomerol.

Pomerol is a small commune adjoining St Emilion making red wine only, again from the Merlot. No classification exists here but the two top wines, Châteaux Pétrus and Le Pin, regularly command prices higher than the first growths of the Médoc.

Burgundy.

Burgundy was probably the first of the French regions to establish a reputation beyond its frontiers, largely because of the interest taken by the Dukes of Burgundy. The first recorded edict to control wine quality was issued by Philip the Bold in 1395. Realising that the Gamay grape did not make good wine in northern Burgundy, he banished it from that area. Demand for fine Burgundy outstrips supply, largely because Burgundian production, excluding Beaujolais, is about 20% of that of Bordeaux. Fine Burgundy is never cheap. Burgundy is in central France, between Dijon and Lyon. It also includes Chablis, 60 miles to the north-west of Dijon, and Beaujolais. The climate here is more continental, characterised by extremes of temperature.

Only four grapes are important; in contrast to Bordeaux, they are largely used unblended. The red wines are made from Gamay in Beaujolais, giving soft, quaffable wines. More serious wines are made further north from Pinot Noir. From the best vineyards very fine wines result, medium in colour relying on high acidity rather than tannin to survive long ageing. Chardonnay makes all classic white Burgundy. Often fermented and aged in wood to add complexity and depth of flavour, Burgundy is the traditional home of that most international of jet-set grape varieties. Perhaps surprisingly, given the grape's international repute, Chardonnay almost never appears on Burgundian labels. Some wine is also made from Aligoté, a lesser white grape, usually sold under a varietal label, *e.g.* Bourgogne Aligoté.

The Appellations of Burgundy.

Most Burgundy is sold under a generic appellation, Bourgogne Rouge and Bourgogne Blanc. A higher appellation is the district one, such as Côte de Beaune or Haute Côte de Nuits. But it is the commune and vineyard appellations on which Burgundy's reputation rests. As in Bordeaux, the districts are divided into communes. Wines produced entirely from grapes grown in a particular commune take its name, *e.g.* Meursault. In the nineteenth century, at a time of poor sales in the area, communes added their name to that of their most famous vineyard, so the commune of Gevrey added the name of the vineyard of Chamertin becoming Gevrey-Chambertin. Nuits-St George and Puligny-Montrachet are other examples.

The best vineyards are classified as *Premier Cru* or *Grand Cru*. In the past one has had to know the long list of these to recognise them from the label. Nowadays most producers are more explicit, clearly boasting of the higher grading.

There are five main districts in Burgundy. From the north the first is Chablis, producing white wine only from Chardonnay. Bone dry and almost flinty in character, Chablis rarely sees oak, so this is unadorned Chardonnay. The Côte d'Or, the golden slope between Dijon and Santenay is the heart of Burgundy. Here some of the most sought after red and white wines in the world are produced. It comprises the Côte de Nuits in the north, largely a red wine area, and the Côte de Beaune, where both Pinot Noir and Chardonnay are grown. Côte de Nuits includes such famous names as Gevrey-Chambertin, Nuits-St Georges and Chambolle-Musigny; the stars of the Côte de Beaune include Meursault and Puligny-Montrachet, Volnay and Pommard. Further south are the districts of Chalonnaise and Maconnais. Here more affordable Burgundies, both red and white are produced, an ideal introduction to the region. In red wine Macon forms the transition between the Côte d'Or and Beaujolais, being a blend of Pinot Noir and Gamay.

Beaujolais.

Beaujolais produces light fruity red wines from Gamay. Most are best drunk young, indeed most Beaujolais is drunk in the year of vintage, as Beaujolais Nouveau, released in November when the wine is two months old. The north of the district produces fuller wines, under the appellations of Beaujolais Villages or, better still, one of the ten communes, the best known being St Amour, Fleurie and Moulin-à-Vent.

Alsace.

Alsace, in north-eastern France, borders Germany. The border has moved at various times in history so Alsace has been German, and the Germanic influence is still visible in the architecture and vineyards of the area. Unusually for French wines, Alsace wines are usually varietally labelled, the most important being: Riesling, Gewurztraminer, Sylvaner, Pinot Gris and Pinot Blanc. A little red wine from Pinot Noir is also produced. Although made from Germanic grapes, and bottled in tall green flutes like Mosel bottles, Alsace wines are distinctly French, made to accompany the rich and diverse cuisine of the region. Unlike most German wine exported, the wines from here are generally dry with strong varietal character. They include the spicy, exotic Gewurztraminer, oily Pinot Gris and steely Riesling. Wines labelled "Reserve" or "Selection" or something similar, are blended from better vats, the pick of the crop. Vendange Tardive and Selection de Grains Nobles are rare and exquisite late picked wines, off-dry to sweet in taste.

Loire Valley.

The Loire is the longest river in France, rising in the Massif Central. Viticulturally only the lower half is considered "the Loire". Each of the four sub-regions – Nantais, Anjou-Saumur, Touraine and the Central vineyards – has its own climate and wines. Most wines are made from one varietal, but here the name of the village or region is paramount. In this northerly part of France the climate is generally cool so white and rosé wines dominate.

Nantais is the home of Muscadet, one of the largest selling quality wines in the UK. Muscadet is the name of the grape as well as the wine, a dry, fairly neutral white wine usually drunk young and fresh to accompany lightly flavoured seafood.

Anjou-Saumur produces mostly dry white wines, from the Chenin Blanc under the Saumur appellation, and red, white and rosé as Anjou. The medium sweet Rosé d'Anjou has been the introductory wine for a generation of British wine lovers. The enclave of Côteaux du Layon produces sweet and medium sweet wine from the Chenin Blanc. This sheltered area, influenced by the river Layon, benefits from noble rot.

Farther up river in *Touraine* Chenin Blanc is joined by Sauvignon Blanc. Sauvignon is often used for the Touraine appellation, but Chenin makes the area's most famous appellation, Vouvray. From one grape a wide variety of styles are produced; dry, medium or sweet, still or sparkling. Confusingly the label does not always reveal the style of wine in the bottle, you need to trust your wine merchant.

The *Central Vineyards* are so-called because they are close to the centre of France. Here Sauvignon produces the famous Pouilly Fumé and Sancerre; appellations for what until recently was universally considered the world's best Sauvignon.

Some red wines are made in the Loire. As well as Anjou Rouge there are Chinon and Bourgueil, made from the Cabernet Franc, and red Sancerre from Pinot Noir.

Rhône Valley.

The Rhône Valley is one of the oldest wine producing regions of France. It is certain that wine existed there by *c.* 600 BC, and it is believed that the steep terraced vineyards of the northern Rhône were the earliest French vine plantations.

Historically Rhône wines were blended with lighter wines, including claret. Recently though their quality has begun to be appreciated, and finally the best are achieving prices comparable with Bordeaux and Burgundy. The region starts south of Lyons at Vienne and extends south to Avignon. It divides neatly in two with a gap around Montélimar, more famous for nougat. The northern and southern districts produce quite different styles of wine, a result of different topography, soils, grapes and climates. Basic Côtes du Rhône can be produced anywhere in the region, but in practice it is nearly always a southern Rhône wine. As with Beaujolais, there is a higher grade, labelled Côtes du Rhône Villages. This is more concentrated and fuller bodied.

The Northern Rhône.

The Northern Rhône comprises a steep hillside, facing east. Here the cliffs are so steep that terraces are required, and all the vineyard functions have to be done by hand. The grape here is Syrah, perhaps now better known by the Australian name Shiraz. Big, full flavoured wines with the structure to age result, sold under the names of the communes such as Côte Rôtie, Cornas and Hermitage. In the middle of the Northern Rhône lie two small, but very prestigious white wine vineyards, Condrieu and Chateau Grillet, producing the epitome of an unusual, flavoursome variety called Viognier.

The Southern Rhône.

The Southern Rhône is less uniform. The valley broadens out to a wide plain, the climate becomes very Mediterranean, with olives and oranges a frequent sight. The range of grapes here also broadens out. Over a dozen different varieties are permitted, but the Grenache is the most widely employed. Relatively pale coloured wines, with high alcohol and little staying power can result, but the majority of producers use judicious amounts of other grapes as improvers to their blends. In contrast to the north, this is the home of large volume average wines plus a few greats, including Châteauneuf-du-Pape, Gigondas and the dry rosé Tavel.

From 1309 to 1378, the Popes lived at Avignon. Pope John XXII built a new palace in the southern Rhône, hence Châteauneuf-du-Pape.

Languedoc-Roussillon.

This great swathe of vineyard extends from the Spanish border to the Rhône estuary and produces one third of all French wines. Once derided, the "Midi" is now a hotbed of innovation in viticulture and vinification. Once the source of much of the EU wine lake, today the emphasis is on quality.

A mix of local grapes goes into the area's appellations, which include Fitou, Côtes du Roussillon, Corbières and Minervois, but it is the international varieties used in the increasingly successful Vin de Pays which are changing the area's reputation.

Famous grapes, handled well, and marketed by variety offer the consumer a reliable and understandable product, at prices which offer excellent value.

GERMANY.

Germany maintains its ranking as one of the chief UK wine suppliers. For many, Germany is the introduction to wine drinking, but there is far more to Germany than Liebfraumilch. Germany's vineyards are in the south of the country, on the limit of vine cultivation. The climate is cool and damp, so the quality of the vintage depends heavily on the weather. The best vineyards are planted on steep south-facing hillsides, suntraps to collect every available solar ray. In such a marginal climate ripe grapes are at a premium, German wine legislation reflects this.

Deutscher Tafelwein and *Deutscher Landwein* are the two grades of table wine. Little is produced and even less exported. About 95% of Germany's wine is quality wine, of which there are two grades. *Qualitätswein bestimmte Anbaugebiete* (QbA, or simply *Qualitätswein*) is the basic category. The wine will come from one of the thirteen *Anbaugebiete* (regions) which is stated on the label.

Each region is divided into districts, *Bereiche*, such as Bereich Bernkastel in the Mosel. Most individual wines come from single vineyards, *Einzellage*. For commercial reasons a group of vineyards producing similar wines may be grouped together into a *Grosslage*; examples include Niersteiner Gutes Domtal and Piesporter Michelsberg. Riper grapes than QbA can go to make *Qualitätswein mit Prädikat* (QmP). Again the wine must come only from the *Anbaugebiet* stated, but it is the level of ripeness, rather than the provenance which gains the wine its esteem. The categories, in ascending order of natural grape sugar at time of harvesting, are as follows:

**Kabinett*, from grapes harvested at the normal time but with higher natural grape sugar. These are amongst the lightest and most delicate of all wines.

**Spätlese* indicates late harvest; a more intense and concentrated style.

**Auslese*, where only extra ripe bunches are selected.

**Beerenauslese* wines are made from individually selected berries, a labour of love. These overripe individual grapes, normally affected by noble rot, produce wines with considerable residual sweetness.

**Eiswein* grapes have their sugar concentrated by freezing, on the vine. Frosts of −8 to −10°C are needed, for a minimum of about eight hours. This freezes the water in the grapes which are pressed when frozen. The resulting juice makes rare wines of great richness.

**Trockenbeerenauslese* is the highest grade, made from individually selected, heavily botrytised grapes which have shrivelled like raisins.

It is the sugar level of the grape, not the wine, which determines the quality level. *Kabinett*, *Spätlese*, and even occasionally *Auslese* wine are available in dry (trocken) styles, although medium sweet is more normal.

Germany has many grape varieties but three are particularly important. Riesling is the finest German grape. Late ripening, but with fine flavours and acidity, it allows wine to mature almost indefinitely. Silvaner ripens earlier than Riesling, giving firm spicy wines. The productive Müller-Thurgau variety was developed because of the climate. It yields generously and is precocious, an insurance against the inclement autumns. Müller-Thurgau accounts for more vineyard area than any other variety.

There are thirteen vineyard regions in Germany, six are important for exports. All follow the routes of Germany's great rivers.

The Mosel.

Mosel-Saar-Ruwer produces pale, light in body yet intensely elegant wines. The steep, south facing slopes of the Mosel and its tributaries, with their slate soil, collect the warmth of the sun to ripen the grapes.

Rheinhessen and Pfalz.

These are the country's two largest regions. Their wines are fuller in style than Mosel. Generically these wines are referred to as "hock", from the village of Hocheim. Most Rheinhessen and Pfalz wines seen in export markets are Müller Thurgau based blends, sold as Liebfraumilch or Niersteiner Gutes Domtal. The vineyards around Nierstein, however, are capable of producing some stunning wines.

Rheingau.

Only here does the Rhine (in German, Rhein) flow east to west, giving the northern bank, the Rheingau, a perfect southerly exposure. Its aspect and topography make this the ideal area for Riesling, representing four-fifths of the regions' vineyards. Rheingau is home to some of Germany's greatest wine estates such as Vollrads, and Johannisberg, and famous villages such as Rüdesheim and Geisenheim.

Nahe.

This area marks the transition between the fuller Rhine styles and the delicate Mosel wines, in addition to producing some Liebfraumilch.

Baden.

Baden, opposite Alsace in the far south of Germany, is becoming important in export markets. The warmer climate permits fuller bodied wines, both red and white. They are mostly dry, and often appear more French, being bottled in shorter, wider bottles, like those used for Burgundy.

Liebfraumilch.

Liebfraumilch is not a region but a style of blended wine. The name originated from a vineyard at Worms in the Rheinhessen, but the wine can come from any one of the four Rhine regions, Rheinhessen, Pfalz, Rheingau or Nahe. The law requires it to be soft, fruity and easy to drink. It must be of QbA status.

ITALY.

So successful is the vine in Italy that the Greeks called the country Oenotria, the land of the vine. Fittingly, Italy is still the world's largest wine producer. Wine is integrally linked to the culture of the country. Wine is a staple part of the diet. A meal is not a meal without wine. As such the wines must match the local food, as diverse and individualistic as the Italian people.

Italy is made up of twenty regions, each individual and each intent on protecting its own identity. It is a long country, covering ten degrees of latitude; the climate, the people and the culture are very different from Piedmont to Sicily.

DOC (*Denominazione di Origine Controllata*) was introduced in 1963 with the rules designed along the same lines as *Appellation Controllée*. Very soon there were hundreds of DOC wines. To differentiate themselves, certain highly reputed areas were granted a higher grading, DOCG (*Denominazione di Origine Controllata e Garantita*). DOCG imposes stricter controls, including mandatory regional bottling and organoleptic analysis. There are currently over a dozen DOCGs, a number which is growing steadily.

Table wine (*Vino da Tavola*) is normally simple, everyday, cheap wine, often sold in two litre bottles. Some producers, however, deliberately break the DOC rules by, for example, growing the "wrong" grape variety. The resulting wine is *Vino da Tavola*, but often more expensive than DOC.

An enormous number of grape varieties are cultivated in Italy. Some, like Nebbiolo, Lambrusco, Sangiovese and Verdiccio are natives, rarely grown elsewhere. There are also historical imports, now naturalised Italians. Pinot Grigio and Merlot, introduced at the time of Napoleon, are widely used in northern Italian wines. Additionally there are the inevitable internationals, Chardonnay and Cabernet Sauvignon.

DOC and DOCG wines always state the area of origin *e.g.* Barolo, Frascati. In some cases the region is prefixed with the grape as well: examples being Barbera d'Alba and Merlot di Pramaggiore.

Principal Wines.

Although Italy produces a vast range of wines, many are not exported in large volumes. The principal export wines are:

*Barolo DOCG – a Nebbilo based red wine from the village of Barolo in Piedmont, the foothills of the Alps. It must be at least three years old before sale, but then has great additional ageing potential. Barolo is a very full bodied wine with high alcohol, tannin and acidity.

*Barbaresco DOCG – is a red wine from the Nebbiolo grape grown in Piedmont. Similar to Barolo in style, though Barbaresco generally is a touch lighter.

*Valpolicella DOC – is normally a lighter red wine made from a mixture of grapes grown in vineyards near Verona, in the north east. Most Valpolicella should be drunk young.

*Soave DOC – a very dry but fruity white wine named after the commune of Soave near Verona.

*Lambrusco – a lightly sparkling and usually medium sweet Central Italian wine from the grape of the same name. Lambrusco is a black grape, so red, white and rosé wines can be made. Most is sold as table wine, but DOC Lambruscos are much finer.

*Pinot Grigio – dry white wine made from the Pinot Grigio grape in many parts of Italy, but particularly in the north east. It is a fresh, fruity wine with a crisp acidity.

*Chianti DOCG – a red wine produced in Tuscany and made from Sangiovese, and other grapes. It can vary in style from light red wines made for early drinking to well-aged wines with great depth of flavour. Chianti Classico, the centre of the area, produces some of the best Chiantis.

*Orvieto DOC – a white wine made in Umbria. Traditionally Orvieto was *abboccato*, or semi sweet, but today most Orvieto is made dry.

*Frascati DOC – is a white wine usually dry, although sweeter styles are permitted under the DOC. It is made just south of Rome. Like many Italian whites, it tends to be light in flavour.

*Prosecco DOCG – made from the glera grape. Only allowed to be called "prosecco" if the grapes are grown in the Veneto or Friuli regions of NE Italy.

SPAIN.

Spain has more land under vines than any other country (though China is a close second), but because of the dry climate, ranks only third in production terms.

Spain's top quality black grape is Tempranillo. Found in both Spain and Portugal, under a whole host of synonyms, this gives the flavour, backbone and structure to all of Spain's top reds. Garnacha is also important, but more for volume. It is widely planted throughout Spain. For white wine the volume grape is Airén, the world's most widely planted variety, all in Spain. It produces refreshing neutral wines if well handled, but is not a high quality grape. Viura is the top white grape.

Spain too has both quality and table wines. Like Italy, there are two categories of Quality Wine, Denominacíon de Origen (DO) and Denominacíon de Origen Calificada (DOC). There are over fifty DOs, and one DOC, Rioja. Little Spanish table wine, *vino de mesa*, is exported as many DO wines represent better value. The most important exports are:

Rioja.

Rioja is in northern Spain, along the banks of the river Ebro, and its tributary the Rio Oja, which gives the region its name. Divided into three (Alta Alavesa and Baja) the main centres are Logroño and Haro. Most Riojas are blended from the different districts and shipped by merchant houses in these two towns. Oak maturation, in American oak casks, gives the distinctive flavour to Reserva and Gran Reserva wines, both red and white. Many Riojas are made without wood.

Navarra.

Navarra is north of Rioja. It enjoys a cool, temperate climate, enabling elegant red and white wines to be produced.

La Mancha.

This area is a vast arid plateau south of Madrid. The climate is extreme, scorching in the summer and very cold during the winter. The largest area of production in Spain, much of the wine goes to brandy production. The light wines, both red and white, are steadily improving.

Penedés DO.

Most Cava, Spain's quality sparkling wine, is produced here, west-south-west of Barcelona. This is also an area of innovation, with modern winemakers using blends of traditional local varieties with international ones.

Other areas becoming more important through recent investment and improvement include Somontano, in the foothills of the Pyrenees and Ribera del Duero on the Duero river.

PORTUGAL.

Northern Portugal comprises a coastal littoral, rising steeply to mountainous inland regions. Further south the plains continue further inland. Atlantic winds bring rain during the winter months and the summers are hot.

Portuguese quality wine is categorised as Denominação de Origem Controlada or Indicação de Proveniencia Regulamentada. Often the label will simply give the catch-all initials of VQPRD. The regional wines, and some of the newer DOC wines from the south, Borba, Palmela, Arruda and Arrabida are gradually becoming more important than some of the classic DOC areas.

Portugal's most popular light wine export, selling in large quantities, is the medium dry rosé Mateus and a similar wine, Lancers. These are examples of excellent wine marketing; having no tradition or history, they were invented for export, and have been amongst the biggest selling brands of wine ever since.

Apart from Port, Vinho Verde and Mateus Rosé few other Portuguese light wines have had much export success until recently. The Salazar regime which came to an end in the early 1970s had imposed restrictive practices on the industry, limiting progress. Following the return of democracy and after joining the EU, Portugal has caught up. Traditional areas are improving, while new areas are now getting more international recognition. The main regions are listed below.

Vinho Verde.

"Vinho Verde" means "green wine" a reference to its youthful character. Fresh in acidity and moderate in alcohol, it is best consumed when young (or green). Vinho Verde is produced in northern Portugal. High trained vines give barely ripe grapes, while enabling other agriculture on the same land. More red wine than white wine is produced, but the red is only consumed in Portugal.

Dão.

Dão is south of the Douro valley in northern central Portugal, a wild and beautiful country with terraced vineyards on granite slopes. Until recently the wines tended to be dried out, aged for too long before sale. Investment since 1986 has now rectified this.

Bairrada.

South of Oporto, between Dão and the Atlantic, Bairrada makes some excellent red wines, sometimes matured successfully for several years.

II. GLOSSARY OF FOOD

Abalone An edible mollusc used in Chinese cooking.

Ackee The fruit of a tree originating in Africa and introduced to Jamaica by Captain Bligh. The creamy flesh of the fruit resembles scrambled egg when cooked and is generally accompanied by salted cod fish.

Aïoli A sauce from Provence made by pounding garlic then adding egg yolks and olive oil to make a garlic mayonnaise. Served separately with an assortment of raw and cooked vegetables and fish or cold meat.

Anchoïade A purée of anchovies, garlic and olive oil served on bread or as a dip with raw vegetables. The word comes from the Provence region of France and is sometimes spelt anchoyade.

Angels on Horseback A hot savoury made with oysters wrapped in bacon, grilled and served on toast. (*See also* Devils on Horseback).

Antipasto Italian starter, from the words for "before meal", consisting of cold meats, olives, marinated vegetables. *etc.*

Avgolémono Popular Greek sauce and also soup, based on eggs beaten with lemon juice. For the sauce, stock from the dish it accompanies is added; for the soup, the eggs are added to chicken stock in which some rice has been cooked.

Bacalao The Spanish word for cod which has been salted and dried. Thus preserved it was for centuries an important winter food in many Mediterranean countries.

Baked Alaska A "surprise" dessert of ice cream baked in the oven which was invented by an American physicist in the nineteenth century. The ice cream and a sponge base are enclosed in meringue, cooked quickly to set the meringue, and served hot. The ice cream remains firm and cold due to the low conductivity of the meringue mixture.

Baklava A pastry dessert from Greece and the Middle East made from thin layers of pastry, chopped nuts and honey syrup, and flavoured with cinnamon. Its origins reputedly go back to the eighth century B.C. in Assyria.

Ballottine Boned meat or poultry dish which is stuffed, rolled and tied up in a cloth, then braised or poached. The word derives from the French for "bale". This was traditionally a Romany method of preparing food.

Balti A slow cooked curry sauce to which meat, poultry, fish or vegetables marinated with spices are added. The balti is the large metal bowl in which the dish is cooked and served and derives from the Urdu for "bucket". The dish was introduced to Britain from Pakistan by the Kashmiri community.

Bamia The Arabic word for okra, a popular vegetable in Middle Eastern cooking. Also known as "ladies' fingers" and in Indian cookery as *bhindi.*

Béarnaise sauce A warm egg yolk and butter sauce similar to Hollandaise (*q.v.*) but with the addition of shallots and tarragon.

Beef stroganoff A Russian dish of sautéed strips of lean beef in a sour-cream sauce with onions and, generally, mushrooms, which became popular in England and the US in the 1930s. Named in the nineteenth century from its association with Count Stroganoff, a Russian diplomat.

Bento Popular Japanese lunch box, consisting of salad, rice, dumpling, pickled vegetables and choice of one meat or fish, all served with miso soup.

Bigos A stew of layers of meat and sauerkraut, the Polish national dish.

Bird's nest soup A Chinese soup made from the lining of birds nests.

Biryani An elaborate Indian dish based on rice cooked with meat or chicken, saffron, raisins and nuts.

Blini Russian pancakes made from a twice-risen batter of flour (wheat, buckwheat or rye), milk, eggs, butter, sugar, salt and yeast. Served with a variety of fillings including sour cream, smoked salmon and caviar.

Bolognaise A traditional Italian meat sauce made with minced beef, onions, garlic, tomatoes and mushrooms served with spaghetti.

Bombay duck A dried fish eaten as a savoury with Indian dishes. Known for its pungent smell, the name comes from the Marathi, "bombilla".

Borscht A traditional Russian soup made from beetroot and cabbage which can be served hot or chilled in warm weather.

Bouillabaisse A Mediterranean fish stew, a speciality of Marseilles. The word is the French interpretation of the Provençal for "boil and settle".

Bresaola Dried salt beef cut in thin slices and served with oil, lemon juice and parsley as an *hors d'oeuvre.* A speciality of Lombardy, northern Italy.

Bruschetta Slices of white bread oven-toasted then rubbed with garlic and moistened with olive oil.

Bubble and squeak An English dish which uses left-over cooked potato and cabbage. The name comes from the distinctive sound the ingredients make when fried together.

Bunny Chow Traditional South African dish of hollowed out loaf filled with curried meats.

Burrito Mexican pancake filled with refried beans and cheese. In Spanish its name means little donkey.

Caesar salad Popular American green salad. The ingredients include lettuce and garlic croutons with a dressing of olive oil, lemon juice, raw eggs, parmesan cheese and Worcester sauce.

Callaloo Caribbean soup made from the fleshy leaves of a tropical root vegetable called Taro. Crab meat is usually added to the soup.

Canelloni The term means 'little tubes'. An Italian dish of pasta squares rolled around a stuffing, usually meat-based, and baked in the oven with butter and cheese.

Carbonara An Italian pasta dish where beaten egg and pieces of ham or bacon are stirred into the cooked pasta. The heat of the pasta lightly cooks the egg, then grated Parmesan cheese is added.

Cassata A block of two differently flavoured ice creams with a filling of cream and crystallised fruits soaked in brandy.

Ceviche Seafood marinated in lime juice, onion and coriander. The national dish of Panama.

Chapati Flat Indian bread made with wholemeal flour, salt and water, fried without fat.

Chicken Kiev Chicken breast folded around chilled garlic butter, then coated in egg and breadcrumbs and deep fried. Not, in fact, from Kiev in Ukraine, it was invented by a Frenchman and given its name later in New York to please Russian immigrants.

Chilli con carne A Texan meat stew meaning 'chilli with meat'. Made with cubed or minced beef, onions, tomatoes and chilli peppers with red kidney beans.

Chop suey A bastardised form of Chinese cooking introduced into the United States to cater for American tastes. It consists of small pieces of meat or chicken cooked with vegetables including bean sprouts and bamboo shoots served with rice.

Chorizo A spicy coarse pork sausage with a distinctive red colour from the addition of paprika, popular in Spanish and Mexican cooking. It can be fresh, as is more usual in Mexico, or cured and air-dried for either eating cold or cooking, as is usual in Spain.

Chowder A thick fish soup originating in Newfoundland, popular in the United States. The most popular version is made with clams. The word comes from the French *chaudière* meaning "stewpot".

Chow mein Stir-fried noodles served with a thick sauce containing meat, fish or vegetables popularised by Chinese cooks in the United States in the 1920s.

Ciabatta An Italian long, wide and flat bread loaf with a soft interior and a crisp thin crust. The word is the Italian for slipper which its shape is thought to resemble.

Cicchetti The Venetian equivalent of tapas (small snacks and side dishes).

Club sandwich Sandwich originating in America made with three slices of bread and two layers of filling.

Coq au vin Classic French dish of chicken simmered in red wine with bacon, onions and mushrooms. Chicken joints are browned then flamed in brandy before adding the wine – a whole bottle of Burgundy is usually specified. The sauce is thickened at the end of cooking.

Corn pone Baked or fried bread made from maize flour and buttermilk, popular in the southern states of America. Pone is a Native American word for bread.

Couscous From the Arabic *kuskus* meaning to grind small. North African ground wheat or semolina which is steamed and served with a sauce or stew of meat or vegetables.

Crème brûlée A dessert of rich custard, made from egg yolks, sugar and cream, topped with caramelised sugar and served cold. French for "burnt cream".

Croquette Small deep fried ball or roll of savoury ingredients coated in breadcrumbs.

Croque-madame A croque-monsieur sandwich *(see below)* topped with a fried or poached egg.

Croque-monsieur French toasted cheese and ham sandwich.

Crudités *Hors d'oeuvre* of pieces of raw vegetables dipped into a cold sauce such as vinaigrette or mayonnaise.

Devils on Horseback A variation on Angels on Horseback (q.v.) substituting plums or prunes for oysters which are wrapped in bacon, grilled and served on toast.

Dhal An Indian dish made of stewed dried peas, onion and spices. Lentils are popular but many varieties of dried peas are used, for example chick peas and mung beans.

Dim sum Small steamed Chinese dumplings usually eaten as a snack. A variety of ingredients are used as fillings in combination or on their own. They include meat, fish, chicken and vegetables. The words mean 'little heart'.

Dolmades Greek dish of vine leaves stuffed with rice, meat and herbs.

Döner kebab The term means 'turning roast meat'. Slices of marinated lamb are packed on an upright spit and the meat is grilled as it turns. The outside layers of cooked meat are sliced as the spit turns.

Dopiaza An Indian curry dish characterised by a large amount of onion, of which part is used in the cooking and the remainder is fried and added at the end. The name is Bengali for "twice onions".

Egg fu yong A Chinese dish traditionally made of egg, white crab meat, spring onions and various seasonings. The name comes from the pink and white Hibiscus flower which the finished dish resembles.

Enchilada Fried Mexican tortilla. These can be filled with meat, cheese or vegetables or any combination of these ingredients flavoured with chilli peppers.

Ertwensoep A thick pea soup from Holland made with pork stock, pig's knuckle, onions and thyme.

Fajitas Mexican freshly-cooked flour tortillas to which diners add their own choice of hot and cold fillings then fold to form a pocket around the filling. They are always eaten with the fingers.

Falafel Seasoned vegetarian patties from the Middle East. Made from chickpeas in Israel and from broad beans in Egypt, where they are called fellafel.

Focaccia Flat Italian bread topped with olive oil, spices and other ingredients such as tomato, making it an early prototype of pizza. Its name evolved from the *panis focacius,* bread cooked in the ashes, of ancient Rome.

Fondue Swiss dish of melted cheese cooked with wine and flavoured with garlic. The dish is eaten as it cooks over a low heat by dipping cubes of bread in the fondue. The word comes from the French and means 'melt'.

Frittata An Italian omelette made from lightly beaten eggs to which a variety of ingredients have been added, usually grated cheese or a chopped cooked vegetable such as onion, spinach or artichoke hearts. It is not stirred in the pan but cooked on both sides like a pancake.

Fritto misto An Italian dish of small pieces of meat and vegetable coated in batter and fried in deep oil. The ingredients are very variable, and in the Milanese version egg and breadcrumbs replace the batter and the frying is in butter. Sometimes short for *fritto misto di mare,* which uses small fish and shellfish.

Galangal Popular flavouring ingredient in SE Asia. Member of the ginger family.

Gazpacho An uncooked Spanish vegetable soup served chilled. Chopped onions, tomatoes, sweet peppers and cucumber are blended with vinegar, oil, garlic and breadcrumbs and ice is added to produce the liquid.

Gnocchi Small Italian dumplings boiled and served with melted butter and grated cheese or with a sauce. Made from either flour, potatoes or semolina, plus eggs. Other ingredients can be cheese, Parmesan cheese and spinach.

Goulash Hungarian meat stew with onions and potatoes seasoned with paprika.

Granita Italian water-ice made by freezing a mix of sugar syrup and either fruit juice or black coffee.

Grissini Italian thin crispy breadsticks, a speciality of Turin where it was invented in the seventeenth century. Considered a more digestible alternative to bread to accompany the *hors d'oeuvre.*

Guacamole A blend of avocado, onion, garlic, lime and coriander, sometimes including tomatoes and chillies. A popular sauce in Mexico, where it is served as a dip with tortilla chips and is an essential accompaniment to *fajitas.*

Gumbo A thick soup from the southern states of America, Gumbo is a name for okra, a vegetable which is one of the main ingredients and gives the dish its smooth, silky texture.

Haggis Sheeps heart, liver, lungs, chopped onions, oatmeal and suet stuffed into the stomach of a sheep to form a large sausage shape and boiled. Usually served with mashed swedes. It is banned in America because it contains lungs.

Halloumi A chewy, squeaky cheese made from a mixture of goat's and sheep's milk.

Halva A Middle Eastern sweetmeat made from ground sesame seeds and honey or sugar. Chopped nuts or dried fruit are sometimes added.

Harissa A fiery condiment of Morocco, Tunisia and Algeria, served with soups and stews. It consists of a purée of red chilli peppers, garlic, cumin and coriander seeds, and olive oil.

Hash The word comes from the French for 'chop up'. Chopped cooked meat (generally corned beef) is mixed with potato and fried or baked.

Hollandaise sauce A warm, slightly frothy, sauce of egg yolks, butter and wine vinegar, served with fish, asparagus or globe artichokes. Although originating in France, its name is from its similarity to earlier Dutch sauces.

Hot-pot A type of baked stew associated with Lancashire consisting of layers of lamb and vegetables topped with thinly sliced potatoes.

Humus A popular Turkish *hors d'oeuvre* made of puréed chickpeas, sesame paste, garlic, olive oil and lemon juice.

Jalfrezi A pungently spicy Indian curry in which marinated pieces of meat or vegetables are stir-fried with green chillies, red peppers, onion, tomatoes and spices to give a dry, thick sauce. Originally an Anglo-Indian dish for using up leftover meat.

Jambalaya A Cajun rice dish which includes beans, shellfish and meat from Louisiana in the USA.

Kebab Small pieces of meat, seasoned, threaded on skewers and cooked over hot embers. This method of cooking meat has been known in the eastern Mediterranean for over 3,000 years. The name may derive from a word meaning "to char".

Kedgeree English breakfast dish of pieces of haddock or kipper cooked with boiled rice and curry paste. The original Hindi recipe consisted of boiled rice and lentils and was called *khichri.*

Korma A rich North-Indian dish of chicken or lamb braised slowly in a marinade of yoghourt and spices. The sauce is often thickened with ground almonds, and sometimes cream is added. Its origin was the Mughal dish of meat braised in oil called *qaurama.*

Lardy cake A sweet sticky English cake made from a white dough mixed with lard, sugar, mixed fruit peel and spices.

Lasagne Italian dish of alternating layers of pasta sheets, Bolognese sauce *(q.v.)* and béchamel sauce, topped with grated Parmesan cheese. Oven baked.

Lassi An Indian yoghurt drink served cold with the addition either of salt or sweeteners such as honey and often flavoured with rose water.

Latke A Jewish pancake made from grated potato with onions and seasoning.

Lobster Newberg A method of cooking lobster originating at the famous Delmonico's restaurant in New York during the nineteenth century. The lobster is cooked in a cream sauce flavoured with wine and paprika.

Loukanika Smoked wine sausages (a Greek dish).

Madras A hot Anglo-Indian curry sauce for beef made from onions, curry powder and tomatoes, with lemon juice added after cooking the meat.

Marinade Process for tenderising and moisturising meat or fish by soaking in a preparation of acid and oily ingredients, for example, wine, olive oil, lemon juice, vinegar, onion, spices and herbs.

Masala The Indian term for a pre-prepared mix of spices for adding to a dish after cooking. In India such mixes are not used for the cooking process itself. The mix we know as curry powder was invented in England in the nineteenth century, when Indian food became popular.

Meze Greek *hors d'oeuvre,* which may include olives, nuts, rice-stuffed vine leaves and tomatoes, tiny onions in a tomato sauce and feta cheese.

Minestrone An Italian soup of various kinds of vegetables with rice or pasta, served with grated Parmesan cheese. The traditional midday soup of agricultural and manual workers in northern Italy.

Mississippi mud pie An American dessert made of a rich smooth caramel fudge and chocolate mousse on a crisp biscuit base. The name comes from its resemblance to the coffee-coloured clay which forms the banks of the Mississippi river.

Moussaka Greece and Turkey both lay claim to being the originators of this dish and it is eaten throughout the Middle East. It consists of layers of minced lamb, fried aubergine, onion and tomato and cheese covered in a white sauce and baked.

Muesli A Swiss breakfast food made of a mixture of oat flakes, nuts and fruit eaten with milk or yoghurt.

Mulligatawny An Anglo-Indian spicy meat soup. There were no soups in Indian cookery and this was invented in Madras for the English there by adapting a medicinal broth known as "pepper water", in Tamil *molo tunny*.

Naan Flat Indian bread cooked in a *tandoor*, a clay oven. The dough is made from flour, salt and yeast moistened with yoghourt. It is served hot brushed with clarified butter called *ghee*, and is the usual accompaniment to a balti curry.

Nachos A Tex-Mex dish of crisp, hot tortilla corn chips covered in melted cheese and sprinkled with chopped, pickled jalapeño chilli. Reputedly created at a Mexican restaurant in 1943 by Ignacio (Nacho) Anaya, as a quick snack for the wives of airmen stationed just over the border in New Mexico.

Nasi Goreng Originally an Indonesian dish very popular in the Netherlands made of cooked rice fried with finely diced meat, chicken and seafood covered with sliced omelette.

Osso buco Italian dish of veal shin which is sawn in pieces, cooked in white wine, stock and chopped tomatoes, and sprinkled with *gremolata*, a mix of parsley, garlic and lemon peel, before serving. The pieces must remain upright while cooking to retain the marrow: the words mean "marrow-bone".

Paella A Spanish rice dish cooked with saffron which gets its name from the pan in which it is cooked and served. The ingredients are chicken, meat, shellfish and vegetables.

Pancetta Italian dry cured pork belly. It can be eaten cold, or cooked and used in a variety of dishes.

Paneer Indian cottage cheese.

Panettone An Italian cake made from a dough of flour, eggs, butter, sugar and yeast mixed with sultanas and spices. A speciality of Milan and a traditional Christmas gift.

Panforte A rich Italian cake from Siena with nuts, citrus peel and spices, especially cloves.

Panini Italian sandwich made from a bread roll, typically a small ciabatta, filled with salami, ham, cheese, *etc*. Sometimes pressed in a grill and served hot. *Panino* is the Italian for small bread roll.

Paratha Indian bread fried on a griddle. The dough is made from wheat flour called *atta* to form a rich, flaky dough which is spread with clarified butter called *ghee*.

Parfait An iced dessert made by freezing in a mould a light, frothy mixture of sugar syrup, egg yolks and whipped cream, flavoured with liqueur or fruit purée.

Pâté Originally this was the French word which described a baked pastry case filled with finely minced meat, fish, poultry or their livers. The modern version is generally served without the pastry.

Pepperpot Caribbean stew consisting of oxtail, calf's foot, salt beef and chicken, vegetables and chilli peppers. The characteristic flavour comes from cassareep, the juice of the cassava root. This flavouring is poisonous unless it is well cooked in the stew.

Pesto An amalgamation of pounded basil, pine nuts, garlic, Sardo or Parmesan cheese, and olive oil, used as a sauce for pasta and fish and as a flavouring for soups. Originally from Genoa, Italy.

Phaal Invented in the UK by Indian restaurants to be the hottest curry known, due to the high quantity of fresh and dried chilli peppers in its thick tomato-based sauce. The name is borrowed from a very hot dish of southern India which it in no way resembles.

Pitta Flat oval bread from Greece and the Middle East. Pitta is served warm, split in half and filled with meat and salad or dipped in humus or taramasalata.

Pizzaiola An Italian sauce of tomatoes, garlic, and oregano or basil, originally from Naples. Traditionally served spread on steak.

Polenta A staple food of northern Italy made by boiling yellow maize flour. Although it can be eaten plain boiled it is usually left to cool then cut up and fried.

Poppadom Round, crisp wafers made from lentil flour eaten to accompany Indian meals.

Profiteroles A dessert made from small balls of a pastry made with eggs and sugar which are filled with whipped cream and covered with chocolate sauce. In fact the French term refers only to the pastry balls, which can also have a savoury filling.

Pumpernickel A German rye bread from Westphalia which, sliced and in sealed packs, can be preserved almost indefinitely. The loaves are baked in a tin very slowly and turn dark brown from the smoke of the beech logs fuelling the oven.

Quiche French cream and egg custard with smoked bacon cooked in an open pastry case. Also known as quiche lorraine it is a speciality of the Alsace-Lorraine region.

Ragù An Italian sauce which is the original, and more elaborate version of, Bolognese sauce. Made from minced beef, chicken livers, bacon, carrot, onion, celery, tomato purée, white wine, butter and nutmeg. In Bologna, milk or cream is sometimes added. Served with many kinds of pasta, especially lasagne.

Raita The Indian term for yoghourt with added ingredients – chopped crunchy vegetables or fruit, most commonly cucumber. Served as a cooling side dish with hot, spicy food.

Rambutan A fruit with pink, hairy berries, related to the lychee.

Ratatouille A Provençal dish of vegetables simmered in olive oil. Typical ingredients are aubergines, tomatoes, red peppers, courgettes and garlic.

Ravioli Small packets of thin pasta filled with a meat or cheese stuffing and poached. Served traditionally either in broth or with butter and cheese. Originally so named only in the Piedmont region of Italy.

Rillettes A French cold *hors d'oeuvre* of potted meat, where the meat is shredded rather than minced. Usually pork, but goose and rabbit are also used. Strips of the meat and pork fat are cooked in a little water then the meat is shredded, put in pots and the fat poured over to seal.

Risotto An Italian dish of Piedmontese rice cooked slowly with butter, onion and the gradual addition of just enough liquid, either water, stock or wine, to give a creamy consistency. This method of cooking rice is unique to Italy.

Rogan Josh A medium-hot dish from Kashmir made from cubes of lamb simmered in a rich red spicy sauce. The Hindus flavour it with fennel seeds, asafoetida and red chillies, whereas the Moslems use garlic, onion and the dried flower of the cockscomb plant, which gives it its red colouring *(rogan* is red in Kashmiri).

Rösti A Swiss dish made by grating cooked potato, pressing it into a cake then frying until one side is brown and crusty.

Salade niçoise A popular French salad based on lettuce hearts, hard-boiled eggs, anchovy fillets, black olives and tomatoes with an oil, vinegar and garlic dressing. Other ingredients, such as cooked green beans, potatoes and tunny fish, may be added. Served as an *hors d'oeuvre* or a lunch dish.

Salami A highly seasoned sausage made from chopped lean pork, or pork plus beef or veal, and fat pork, cured with salt then air-dried. The process originated in Italy to preserve meat for the winter. The word is derived from *sal*, the Latin for salt.

Salsa A type of sauce originating in Mexico in which fresh or cooked vegetables or fruit are coarsely cut up and flavoured with herbs and spices. It can be served as a relish or poured over food. The term is the Spanish for sauce.

Saltimbocca An Italian dish of thin slices of veal and ham topped with a sage leaf, rolled together and cooked in butter and Marsala. The word means "jump into the mouth".

Samosas Triangular shaped pastries, deep fried, and filled with potato, vegetables or *keema* (minced lamb). Often flavoured with coriander. A popular Indian dish.

Sandwich Savoury filling between two pieces of bread made popular by the Earl of Sandwich in the eighteenth century. He was unwilling to stop playing cards and asked for a piece of cold beef between two slices of toast.

Sashimi Japanese dish of thin slices of raw fish served with soy or horseradish sauce.

Satay A dish originally from Indonesia and Malaysia, where it is called *sate*. Little skewers of meat, chicken or fish, are marinated with spices then barbecued. The characteristic yellow colour is due to the turmeric used in the marinade. Often served with a spicy peanut sauce.

Sauerkraut Traditional German dish of pickled cabbage. Cabbage is packed with salt and ferments to give it a sour taste. This is also a method of preserving the cabbage.

Shashlik The type of kebab (*q.v.*) popular in the countries of the former Soviet Union and in Mongolia. Meat is marinated overnight before the cubes are threaded on skewers and grilled. Vegetables such as onion and tomato are often interspersed on the skewers.

Shish kebab The term used in the Middle East for the same type of kebab as shashlik (*q.v.*) although the meat is not normally marinated. The words mean "skewered roast meat".

Simnel cake A fruit cake with a layer of almond paste in the centre and topped with almond icing. The traditional gift on Mothering Sunday from daughters away in domestic service.

Skordaliá Greek *hors d'oeuvre* consisting of an amalgamation of garlic mayonnaise, ground almonds, breadcrumbs, lemon juice and parsley.

Smörgåsbord A Swedish buffet meal consisting of a variety of dishes from which a complete meal may be chosen. Smoked or pickled fish, cheese, butter and bread are basic items, others are hot and cold meats, salads, eggs and fruit. The name is from *smörgås* (open sandwich) and *bord* (table).

Spam A processed meat product. Originally from the USA the name comes from spiced ham. It was popular in Britain during the Second World War as a substitute for meat.

Stir-fry A traditional Chinese method of preparing small uniformly sized pieces of food quickly in a wide, deep, pan with a curved bottom made from thin metal called a wok. Its shape ensures that only the bottom of the pan gets hot.

Stollen A German loaf-shaped Advent cake containing dried fruit, candied peel and spices, and sprinkled with icing sugar. A speciality of Dresden. The word means "tunnel", possibly referring to its shape. Stollen dates from the middle ages.

Strudel A traditional pastry of Austria and Hungary, made by spreading a filling on very thin pastry then rolling it up and baking in the oven. The most popular filling in Austria is apple with raisins and cinnamon; in Hungary, poppy seeds and sour cherry. *Strudel* is the German for swirl.

Sukiyaki A Japanese dish of thinly sliced beef, vegetables, beancurd, soy sauce, rice wine (*sake*) and sugar. The dish is cooked at the table. It is said to have been introduced as a means of getting the Japanese to eat more meat.

Summer pudding An English dessert of lightly cooked raspberries and redcurrants encased in soft white bread and chilled overnight so that the juices flavour and colour the bread.

Sushi Japanese snacks consisting of small squares or balls of cold boiled rice mixed with seaweed, vinegar, salt and sugar. These are covered with a variety of food such as mushrooms, fish or omelette.

Tabbouleh Middle Eastern salad made with cracked wheat, herbs, onions and tomatoes.

Taco Filled Mexican pancakes made of wheat or maize flour which are shaped and fried. The traditional filling consists of a mixture of minced beef, beans and a rich tomato sauce flavoured with onions and chilli peppers.

Tagliatelle The most common form of home-made pasta in Italy. A paste of flour and eggs, rolled out and cut into strips, then boiled and served with either butter and Parmesan cheese or with a sauce.

Tajine North-African slow-cooked stew of meat, poultry or game with vegetables, spices and such fruit as olives, apricots and preserved lemons. The name is from the pot it is cooked in, a heavy clay pot with a circular shallow base and a large cone-shaped cover.

Tandoori A *tandoor* is the Urdu term for a clay oven. A variety of Indian dishes cooked in this way are given the name tandoori, chicken being the most well known.

Tapas Savoury snacks served in Spanish bars.

Tapénade A Provençal sauce of pounded black olives, anchovy fillets and capers blended with olive oil and lemon juice. Traditionally served with hard-boiled eggs as an *hors d'oeuvre*. The word comes from *tapéno*, the Provençal for capers.

Taquitos Mexican miniature tacos (*q.v.*).

Taramasalata Greek *hors d'oeuvre* of pink cod's roe, garlic, lemon juice, olive oil and breadcrumbs mixed to a paste.

Tempura Japanese method of deep frying seafood and small pieces of vegetables coated in a light batter.

Teriyaki Japanese method of cooking fish or, more rarely, meat, from *teri* (glaze) and *yaki* (to broil). The food is sliced and broiled or grilled with a marinade of soy sauce, *mirin* (Japanese sweet cooking wine), and sugar or honey. The sweetness gives it a characteristic shiny appearance.

Terrine Originally this was the French word for a round or oval earthenware cooking pot, fairly deep and without handles. It came to mean the food cooked in it, and the meaning is now essentially the same as pâté.

Textured vegetable protein A type of meat substitute made from soya beans first marketed in the USA. A paste of soya beans is spun into fibres and formed to resemble meat.

Thali A complete Indian meal of several dishes on a single platter – the traditional family way of eating in the Indian sub-continent.

Tikka Indian dish of grilled marinated chicken pieces on skewers.

Tiramisu An Italian cake made from sponge biscuits soaked in espresso coffee, layered with a mix of cream cheese, egg yolk, sugar and, optionally, Marsala wine, and topped with cocoa. The word means "pick me up".

Toad-in-the hole Fried sausages baked in batter.

Tofu The Japanese name for a kind of cheese made from soya bean milk. It is also popular with vegetarians as a source of protein.

Tortellini Little coils of pasta filled with a rich stuffing and served either in broth or with cheese and butter. A speciality of Bologna, Italy, where it was the traditional dish on Christmas Eve.

Tortilla Flat Mexican pancakes made from cornmeal flour, water and salt, filled with a variety of ingredients such as meat, chicken, refried beans, cheese and salad.

Tournedos Rossini Sautéed medallions of beef fillet topped with foie gras and truffles and served on croûtons with a Madeira sauce. Reputedly created for the composer Rossini.

Tzatziki Greek dip made from cucumber, garlic and yoghurt.

Vinaigrette A salad dressing made from oil and vinegar.

Vindaloo Very hot Indian meat or chicken curry. The addition of vinegar gives this dish its characteristic flavour.

Vol-au-vent French pastry cases filled with meat, fish or other savoury fillings in a creamy sauce. Usually eaten as snacks with drinks.

Waffle American batter cakes cooked in a waffle iron which gives them their distinctive honeycomb appearance. Served warm with maple syrup and butter.

Wasabi A fiery green vegetable used in Japanese cookery. The grated root is similar to horseradish and is often served with sushi.

Waterzooi A Flemish freshwater fish stew. The word is from the Flemish for "water" and "lot".

Wun tun Savoury Chinese dumplings usually made from wheat and filled with meat, fish or vegetables in a seasoned sauce. They are either fried or boiled in a thin soup.

Yoghurt Milk curdled by the action of heat and bacteria to produce a thick liquid with a creamy texture and sharp flavour. It is known to have been eaten in the Middle East at least 8000 years ago. Sales of frozen yoghurt are now rising fast.

Yorkshire pudding English savoury batter pudding made of eggs, flour and salt, baked in the oven and eaten traditionally as an accompaniment to roast beef, potatoes and vegetables, with gravy.

Zaalouk A popular Moroccan dish of roasted aubergine, with various spices added. Often served cold with pitta bread.

Zabaglione Italian name for a frothy custard type pudding served warm and made from Marsala, Madeira or other sweet wine, egg yolks and caster sugar.

Zuppa Inglese Italian trifle made with macaroons soaked in alcohol and covered with cream cheese.

III. BEER AND LAGER

ABV: alcohol by volume.

ale: although the terms 'ale' and 'beer' are sometimes used as virtual synonyms, the description 'beer' was first introduced in the late Middle Ages to designate ale to which hops *(q.v.)* had been added.

Ale had been drunk for at least 4,000 years and was known to the ancient Near East, the Celts and the Anglo-Saxons. Modern ale is fermented at higher temperatures (15–23°C) than lager *(q.v.)* beer and is preferably brewed from winter barley, which gives the ale a robust quality, and in Britain uses fertilised female hops which add an earthy and peppery aroma and flavour to the ale, together with considerable bitterness. Traditionally brewed in hard-water areas rich in minerals. The main styles of ale are old ale, barley wine *(q.v.)*, Dubbel and Trippel *(q.v.)* brown ale, pale ale, porter including stout *(q.v.)* and wheat beer.

barley: recognised for centuries as the best grain for brewing and comprises 30–50% of the grain used, even in 'wheat beers'. Characterised as two-row or six-row depending on the number of rows of grain within each ear, the two-row variety has traditionally been preferred for brewing. Czech and German lager brewers have normally insisted on the two-row variety. The best two-row barley, known as 'maritime barley', grows on the rich, dark soils near the sea in East Anglia, the Scottish lowlands and Belgium.

The tannins in the husk of the six-row variety, which is the norm in the Mediterranean countries and in the United States, can give rise to a 'haze' in the beer which has to be dispelled by additives, such as corn or rice.

barley wine: a style of strong ale originating in nineteenth-century England, but now brewed worldwide. The name derives from its strength of 8–12% ABV which is comparable with that of wine.

bitter: a beer which exploits the bitterness inherent in fertilised hops. The Admiral and Golding varieties of hop are particularly suitable.

brown ale: a description dating from the late seventeenth century, but which has tended to change its meaning over the years. Modern brown ale is dark in colour with the flavours of caramel and chocolate.

Dubbel/Double: The Flemish and French names for the medium-strength (6–7.5% ABV) dark abbey beers, not brewed by monks but in the monastic style.

Guinness: The world's most famous creamy stout, now brewed in more than 150 countries worldwide. Since 2005, however, all the draught Guinness sold in British pubs has been brewed in Dublin, where Arthur Guinness signed a lease on the St James's Gate brewery in 1759.

hops: contrary to much popular belief, hops are not an essential ingredient of beer but are an adjunct to counter both the sweetness of the malt and its susceptibility to bacterial infection. They only appeared in England in the late fifteenth century and their use was banned initially by, amongst others, Henry VIII for the royal breweries, and the city of Norwich. Hops had, however, been used in brewing in central Europe since the eighth century A.D.

Modern English hop-growing is concentrated in Kent and Worcestershire and Britain remains distinctive in allowing the male hop to mate and in exploiting the bitterness and earthiness associated with the fertilised plant.

The citric quality given to beer by the addition of hops is, however, at its most marked with the US varieties, with the Chinook bestowing a strong taste of grapefruit.

hops, noble: the hops grown in such celebrated central European regions as the Hallertau in Bavaria and Zatec in the Czech Republic, and which are renowned both for their aroma and their limited bitterness.

kriek: Belgian fruit beer. The name is from the Flemish word for black cherry, but other soft fruits, particularly raspberries, are often used. The use of fruit to flavour the beer is thought to pre-date the use of hops. *Oude kriek* (old black cherry) is an earlier cherry-steeped lambic beer *(q.v.)* which is now rarely found.

lager: a generic name for the lighter, smoother and softer beers traditionally associated with the German-speaking regions of central Europe, *Lagerbier* literally meaning 'beer for keeping'. It is now, however, produced all over Europe and elsewhere. Lager is typically fermented at 7–12°C.

Lager only became popular in Britain in the years following the Second World War, and many of the most famous continental brands, though by no means all, are now brewed in Britain under licence.

Lager brewing is traditionally associated with soft-water areas and prefers to use spring barley which gives the beer its lighter and softer qualities. It also relies on unfertilised hops to avoid astringency and any significant bitterness.

lambic: a style of Belgian beer, produced by spontaneous fermentation in open vessels in brewery attics as a result of the yeast in the air. It is the style of beer most similar to wine produced anywhere in the world, with a refined but acquired taste. 'Faro' is a variety of lambic sweetened with sugar.

malt: the modified barley created by the processes in the maltings *(q.v.)* which has a natural biscuity sweetness.

– '*dark malt*': malt which has been heated to the highest temperature and is used for the brewing of darker beers such as English mild.

– '*green malt*': malt heated to about 60°C so as to dry it and thereby halt the germination process while preserving the enzymes which will convert the starch into sugar in a later stage in the brewing process.

– '*pale malt*': malt heated to a higher temperature than 'white malt' and traditionally used for ale brewing.

– '*smoked malt*': malt dried over the traditional variable wood fires which acquires a distinctive smoky taste. Still used for the production of some German beers *(Rauchbier)*.

– '*white malt*': malt heated to a temperature slightly above 60°C which is maintained over 24 hours. Suited to the brewing of lager beers.

maltings, the: the part of the brewery where the grain is 'steeped' or soaked to remove impurities and to allow germination to start. In a traditional brewery, the grain was spread over a floor as a 'couch', but it is more normal now to rely on large revolving drums. The resulting 'modified' barley is known as 'green malt' *(q.v.)*.

mild (ale): dates back to early seventeenth-century Britain, if not earlier, and originally meant young as distinct from aged ale, but now implies 'mildly hopped'. It has been largely superseded by bitter and lager, particularly in the south of England, and now only around 10% of the beer sold in British pubs is mild.

minerals: a feature of hard waters which helps to give pale ales their distinctive character. Amongst the more significant is calcium sulphate, or gypsum, which prompts enzymes to turn starch into sugar during 'mashing', stabilises the unfermented beer, and activates the yeast. The waters of Burton-on-Trent are rich in gypsum.

oast house: an integral part of the traditional Kentish landscape, the cowl of the oast house ensured a steady draught of warm air over the hops to prevent them from going mouldy. Largely superseded by more industrialised methods, most oast houses have now been converted to domestic use.

oats: used to a limited extent in the brewing of some stouts, but they result in too creamy a flavour for general use.

pale ale: first meant a lightly hopped ale, much less bitter than its modern descendants, but is now a comprehensive term for a wide range of beers derived from predominantly pale malts. It covers English bitter, India pale ale, and strong pale ale of which the ABV can reach 12%, although as much as 29% has been recorded.

Pedigree: a popular, highly-rated beer brewed by Marstons since 1952. Its strength is 4·5 abv.

Pils: short for Pilsener, from the German form of the town of Plzeň, a great brewing centre of the Czech Republic. Most modern lagers are based on the original Pilsner style. Colloquially used as an alternative to 'lager' *(q.v.)*.

porter: a dark beer, which took its name in the eighteenth century from London's street porters. A strong porter was a 'stout porter', subsequently shortened to stout *(q.v.)*.

Reinheitsgebot **(purity law)**: the German law dating from the sixteenth century which stipulates that only malted barley or wheat, together with hops, water and yeast, may be used in the production of beer. The law can be seen as setting a 'gold standard', but its proscription of the sugars and unmalted cereals which give such famous beers as English pale ales and Irish stouts their distinctive colours and flavours renders them technically 'impure'.

rice: often used for brewing in the Far East where barley is usually difficult to cultivate.

sorghum: a cereal often used for brewing in Africa where barley is usually difficult to cultivate.

Stella Artois: one of the world's best-selling beers and originally from Leuven, Belgium, but now additionally brewed elsewhere under licence. It is the top-selling beer in Britain and, at 5.1% ABV, marginally stronger than most other lagers.

stout: beer with marked 'body' or density. Guinness *(q.v.)* is probably the most famous such stout.

Trappist beers: the strong, dark beers brewed in Belgium and France by the monks of the reformed Trappist branch of the Cistercian order. The reformed rule was first established at the abbey of La Trappe in Normandy, but the six approved monastery breweries are at Achel, Chimay, Orval, Rochefort, Westmalle and Westvleteren. *See also* ***Dubbell/Double*** and ***Trippell/Triple***.

Trippell/Triple: The Flemish and French names for the strong (7.5–9.5%) amber-coloured abbey beers.

water: an easily overlooked but vital element of beer, constituting 90% of even the strongest. The essential distinction is between hard and soft waters, with the former being needed for pale ales and the latter for lagers. The water of Burton-on-Trent, the home of English pale ales, is notably hard and also rich in salts, whilst that of such famous lager-brewing centres as Ceské Budějovice and Plzeň in the Czech Republic and Munich, Germany, is very soft with minimal mineral content.

wheat beers (white beers): brewed from wheat rather than exclusively from barley, although barley still constitutes 30–50% of the total grain. Despite the great increase in the popularity of wheat beers in recent years, wheat still constitutes only 1% of all the grain used for brewing across the world.

yeast: added to ferment the beer, and the variety chosen has an effect on the aroma and taste of the final beer.

IV. SPIRITS AND LIQUEURS

SPIRITS

Spirits are liquids of high alcoholic strength made by distilling lower strength liquids which have been obtained from the fermentation of a base substance. This base is most commonly either grape juice, a "mash" of grain, or a sugar solution, but other fruit juices and even certain vegetables are also used. For a grain base, the starch is first converted to sugar by a process known as "malting".

The distillation process consists of heating the alcoholic liquid from the fermented base until it vaporises then cooling the vapour until it condenses. The resulting liquid (the distillate) contains alcohol plus some water vapour carrying the flavour of the base. Successive distillations, known as "rectification", increase the alcoholic strength and refine the flavour, sometimes until it disappears altogether, as in many vodkas.

The distilling apparatus is either a pot still or a continuous still. The pot still, shaped like an onion with a spout coming from the top, is not ideal for commercial use as the still must be refilled for each distillation. It does, however, retain more of the flavour of the base and is therefore used for cognac, Scotch and Irish malt whiskies and most rums. The continuous still allows an uninterrupted flow of liquid through rectifying columns. This produces a high strength, colourless and sometimes odourless and tasteless spirit, and is used for grain whisky, gin and vodka.

Aguardente de Caña: A Brazilian spirit distilled from sugar cane sap, literally "cane liquor", it is similar to unmatured white rum. Known as *Cachaça*.

Akvavit or **Aquavit:** A Scandinavian grain or potato spirit flavoured with spices, made in a similar way to flavoured vodkas. Also called *schnapps*, from old Nordic *snappen* to snatch, from being snatched down the throat in a single gulp.

Arak (or **Raki**): Perhaps the first spirit ever distilled, allegedly from 800 B.C. in India. Its name is from the Arabic for juice or sap. As Raki, the national spirit of Turkey.

Barack Pálinka: A Hungarian spirit distilled from apricots.

Bitters: The term for any spirit flavoured with bitter herbs or roots. The best known is *Angostura Bitters* which uses gentian on a rum base and is named from the town in Venezuela where it was created by Simon Bolivar's doctor for his troops. Now made in Trinidad, it is principally used for making "pink gin". Other bitters include: *Amer Picon* from France, with a brandy base with gentian, quinine and orange peel; *Campari* and *Fernet Brance* from Italy, both with bitter orange peel; and *Underberg* from Germany.

Brandy: Any spirit distilled from wine. The name is from the German *Gebranntwein*, "burnt wine", via Dutch *brandewijn*. Brandy in some form is made in all wine-producing countries, but the most famous are Cognac and Armagnac from France.

Types of Brandy

Armagnac: Brandy distilled from white wine produced in the Armagnac region in Gascony, France, where it has been made since the 15th century. The wine must be from specified vines within a limited area which is divided into three sectors: *Haut Armagnac, Ténarèze*, and *Bas Armagnac*. The finest are from a single area, with the best from *Bas Armagnac*. A blend from more than one sector is described simply as *Armagnac* and labelled according to how long it has been aged in cask: VS/Three Star for 3 years, VO/VSOP/Réserve for 5 years, Extra/XO/Napoléon/V.A.Réserve for 6 years.

Unlike cognac, armagnac comes from a blend of several varieties of grape, is usually distilled in a continous still, and is matured in barrels of local black oak.

Asbach Uralt: a German brandy matured in the same way as cognac and aged for 18 months.

Cognac: Brandy distilled in a pot still from white wine produced from vines grown around the towns of Cognac and Jarnac in France, and aged in Limousin oak casks. Only a single variety of grape, Ugni Blanc, is normally used. The best cognacs are defined by the area of Cognac the grapes come from: Grande Champagne produces the finest cognac, Petite Champagne the next in quality; Fine Champagne is a blend of the two. Blended cognac is defined according to the minimum time it must be aged: VS for 3 years, VSOP for 4 years, and Napoléon, XO and Vieille Réserve for 6 years.

Cognac has been made since the 17th century and is thus a newer brandy than armagnac. The vast majority of cognac is sold to China.

Metaxa: A blend of Greek brandy and sweet Muscat wine from the Greek islands of Samos and Limnos, invented by Spyros Metaxas in 1888.

Pisco: A fine quality clear brandy distilled from Muscat grapes in Peru and Chile. Aged but always colourless as the barrels are so old they have no colour left to impart.

Spanish brandy: Distilled around Jerez using grapes from La Mancha and matured in a solera system in the same way as sherry. Spain is the most significant producer of brandy after France, for both quality and quantity.

Brandy (fruit): Although strictly speaking brandy is a spirit distilled from wine, in practice the term is applied both to some liqueurs (*see* Apricot and Peach Brandy in *Liqueurs*) and to the fruit spirits distilled from fruits other than grapes and made principally in France, especially in Alsace, where they are known as *eaux de vie* or *alcools blancs*. They are also found in Switzerland and Germany. Such spirits are not sweetened and are appreciably stronger than the corresponding liqueurs. They are colourless because not aged, and have a clear pure scent and flavour of the fruit.

Varieties of fruit brandy include: *Framboise* (raspberry), *Mirabelle* and *Quetsch* (types of plum), *Poire Williams* (pear), *Mûre* (blackberry), *Fraise* (strawberry), and *Myrtille* (bilberry). *Kirsch* and *slivovica* (q.v.) are also fruit brandies.

Calvados: Produced in the Calvados region of Normandy, France, by distilling cider. The resulting spirit is aged in oak barrels for at least two years and can be for up to 40 years, which gives it its colour and subtle flavours. Similar labelling to that of cognac is used to indicate its age. The best calvados is from the Pays d'Auge, where the pot still must be used. Other areas use both methods of distilling. The first mention of the spirit was in 1553 and a guild for its distillers was formed in 1600.

A spirit made from apples is made also in New Jersey, USA, known as Applejack.

Gin: Originally a Dutch medicinal concoction of the late sixteenth century which flavoured a neutral grain spirit with juniper berries. Known in Britain as Geneva or Genever from the French *genièvre* (juniper) or as Hollands from its Dutch distillers. Its effect on the then British soldier was dubbed "Dutch courage". It became increasingly popular after William III raised the duty on French wines and brandies, resulting in such widespread drunkenness that in 1736 a tax was imposed which had the effect of prohibiting it to all but the rich. The result was serious riots in London, and the tax law was repealed in 1743. Consumption continued apace, graphically shown in Hogarth's picture of 1750, Gin Lane, but it eventually changed its image from the curse of the urban poor (it was known as "mothers' ruin") to respectability via the cocktails of the 1920s.

Gin today is distilled from grain or molasses and must by law be flavoured with juniper berries, but other "botanicals'" such as coriander seeds, orange and lemon peels, and angelica are used to give a distinct flavour to different products. Modern "boutique" gins are now experimenting with diversified flavours and colours, as in the deep orange Saffron Gin.

Types of gin

Genever: A highly aromatic gin from its use of malt wine, a strong grain spirit made from malted barley. There are two versions: *oude* (old) and *jonge* (young), of which *oude* has a higher proportion of malt wine and so more aromatic than *jonge*, which is drier. Also known as "*hollands*".

London Dry Gin: An unsweetened gin from unmalted grain, originally made only in London. Now describes this particular style which may be produced anywhere.

Old Tom Gin: A sweetened gin which is now rare. The name is said to be derived from a container once used for dispensing the gin, which was in the shape of a tom-cat—payment was put into the cat's mouth and the gin was served through the cat's paw!

Plymouth Gin: Made only in Plymouth and the original gin used with Angostura bitters to make "pink gin". Originally more aromatic than London gin, but now drier.

Grappa: Italian spirit from the grape residue after making wine. (*See* **Marc**).

Kirsch: A fruit brandy distilled from the juice and ground up stones of Morello cherries. Often used in desserts. A true fruit spirit, unsweetened and not to be confused with cherry brandy. Made in eastern France, the Black Forest region of Germany, Switzerland and Austria.

Marc de (Bourgogne, Champagne etc.): Spirit made by distilling the grape residue left after extracting the juice to make wine. Made in the French regions of Burgundy, Champagne, Alsace, Provence and Jura. Also made in Italy where it is called *grappa* and Germany where it is called *Trester Schnapps*.

Mescal/Mezcal: The generic name for spirit distilled in Mexico from the fermented juice of the blue agave plant, after the art of distilling was introduced into Mexico by the Spaniards in the 16th century. The juice is extracted from the *piña*, the huge (50kg) fruit resembling a pineapple at the heart of the plant. One type of mescal has a *maguey* worm (actually a moth larva) in the bottle, originally placed there to show by its preservation the strength of the spirit. Tequila is a refined version of mescal.

Rum: A spirit distilled from sugar cane products, first produced in the 17th century in the West Indies which is still its main source. Puerto Rico is the world's biggest producer. It is usually made from molasses, the by-product of sugar production, but the finest rum is made from pure cane juice. Both methods of distillation are used but the best rums are double-distilled in a pot still. The name is probably an abbreviation of the Latin for sugar, *saccharum*.

In the 18th cent. ratings in the Navy were given a daily ration of half a pint of rum as it could withstand heat better than beer. This practice remained (albeit reduced to a third of a pint!) until 1970.

Types of rum

Dark Rum: Full-bodied rum matured usually for five years in old bourbon whiskey barrels. Then its colour is sometimes enhanced by caramel before bottling. Made in Jamaica and Guyana (where it is called Demerara after the river) from molasses, in Haiti it is made from cane juice.

White Rum: Clear, dry, light-bodied rum from Cuba and Puerto Rico, made from molasses distilled in a continuous still then either bottled immediately or matured for just one year.

Golden Rum: White rum which is matured for three years in charred barrels, which produces a mellow flavour and golden colour.

Slivovica: A spirit distilled from the juice and stones of small black plums. Made primarily in the former Yugoslavia but also in other eastern European countries.

Tequila: A clear or golden spirit from a double distillation of mescal (*See* **Mescal**), named from the town in Mexico where it was first made. Some tequilas are blended with cane spirit, but by law must contain at least 51% agave spirit. Tequila can be matured in wooden casks, which produces the different types: *joven* or *blanco*, less than 60 days; *reposada*, 2–6 months; *anejo*, a year or more. *Curados* is *joven* tequila which has been flavoured.

Sales of tequila are soaring with the growing popularity of Mexican new-wave restaurants.

Vodka: Vodka, "little water", is an almost neutral spirit which has been made in Russia and Poland from at least the twelth century but is now produced in many other countries. The base is grain or molasses, or even potatoes though this is rare. The fermented base is twice distilled then filtered through charcoal to remove any unwanted flavours. Like most spirits it was originally medicinal. In Russia it is drunk as part of a meal but in the west, since it is almost tasteless, it is mainly prized as a mixer.

Straight vodkas are not aged but there are some traditional flavoured vodkas which often are: *Wisniowka* is a Polish vodka flavoured with cherries; *Zubrowka* is a Polish rye-based spirit with a blade of bison grass, zubrowka, steeped in it; Gold Vodka, or *starka*, is a Polish vodka aged in wooden casks for 5–10 years and *winiak* has a dark gold colour from aging in old wine casks; Pepper Vodka, or *pertsovska*, is infused with hot and mild red peppers, allegedly from a recipe by Peter the Great.

Nowadays there is a great variety of flavourings, such as lemon, berries, and pepper, found in vodkas produced outside eastern Europe particularly in Sweden, which has also introduced a sparkling vodka. There is even a marmalade vodka produced in Herefordshire by redistilling a potato-based vodka with marmalade and Seville orange peel!

Whisk(e)y: A golden brown spirit distilled from grain, originating in Ireland from an unknown but early date and in Scotland from at least the 15th century. Its name is from the translation of the Latin "*aqua vitae*" into Scots Gaelic as *uisge eatha* and into Irish Gaelic as *usquebaugh*, which by the mid-18th century had become anglicised to whisky in Scotland and whiskey in Ireland. For some time little known outside their home countries, the prime cause of its rise in popularity elsewhere was the phylloxera epidemic of 1870–1900 which largely destroyed the vineyards of Europe. With popularity came imitation and whiskies are now produced all over the world, the best being from Scotland, Ireland, the USA and Canada. The name is "whisky" in Scotland and Canada and "whiskey" in Ireland and the USA.

Scotch Whisky

There are two distinct types made in Scotland: malt whisky and grain whisky. These can be blended to form a third type.

Malt whisky: The most highly prized Scotch whisky. Made from malted barley which has been dried over a peat fire, giving the whisky a distinctive smoky flavour. It is double-distilled in a traditional pot still and matured for 3–20 years. *Single Malt* whiskies are from a single distillery, the most renowned being on Speyside (*e.g.* Glenfiddich and Glenlivet). The rarer *Vatted Malt* whiskies are a blend of single malts.

Grain whisky: Made from both maize and malted barley, distilled in a continuous still and matured for 3 years. A light whisky, quick to mature.

Blended whisky: A blend of malt and grain whisky, lighter than a pure malt. Could not legally be called whisky until 1909.

Irish Whiskey

Made mainly from barley but only a small amount is malted and some oats are added. The process is similar to that for Scotch malt whisky, using a pot still, but the barley is dried in a kiln rather than over a peat fire. It is matured for 5–12 years.

American Whiskey

There are several types. The best are *Bourbon* and *Tennessee*. All are made using the continous still.

Bourbon: A lighter whisky than Scotch, made from at least 51% corn plus malted barley and a little rye then aged for at least one year in single-use charred oak casks. It can only be produced in Kentucky, where it originated in the 18th century.

Corn Whiskey: Made from a minimum 80% corn and aged in uncharred casks.

Light Whiskey: Made from mixed grains and is similar to, but stronger than, *corn whiskey*.

Rye Whiskey: Made in the eastern states from 51% rye and aged in uncharred casks. Also made in Canada.

Tennessee Whiskey: Must be made from 51% of any grain, but usually corn or rye, and is filtered through charcoal. Can only be made in Tennessee.

Canadian Whisky

Smooth, light whiskies made using a similar process to *bourbon*, traditionally with a rye base but often with a higher proportion of corn than rye. Other cereals are added for flavour.

LIQUEURS

Liqueurs are spirits which are blended with a flavouring and then sweetened, and sometimes artificially coloured. The most common flavourings are herbs and fruits, but roots, barks, seeds, spices and flowers are also used. The first known liqueurs were made by monks from their local herbs and were primarily for medicinal use. As enjoyable drinks, liqueurs are now found all over the world, from Japan to Mexico and even in the UK, notably at Lurgashall in Sussex.

The best liqueurs are made by steeping the flavourings in the spirit which is then redistilled, but other methods of extracting the flavours which do not involve distillation are also used, such as maceration.

The following list is not exhaustive but is intended to include most of those which may be encountered with an indication of their flavour.

Advocaat: A Dutch low-strength liqueur made from egg yolks, sugar and brandy. Thick, yellow and creamy, it is a version of egg nog but without milk. Mixed with lemonade it makes a "snowball".

Amaretto: Made from almonds and apricot kernels steeped in brandy. Allegedly first made in Saronno, near Lake Como, Italy, in 1525.

Anisette: An aniseed-flavoured liqueur from France. The recipe is said to have been inherited by Marie Brizard from a West Indian in the 18th century.

Apricot Brandy: An infusion of apricots in brandy, usually from France or Holland.

Aurum: Named from the Latin for gold (allegedly by D'Annunzio), this may refer to its colour or it may have originally contained gold flakes. Made by distilling brandy infused with orange peel and whole oranges then blending this with 4-year-old brandy, adding saffron to enhance the golden colour then maturing in wood. From the Abruzzi mountains in Italy.

Bailey's: A blend of double cream, Irish whiskey, neutral spirits and chocolate, made in Dublin, Ireland. This was the original cream liqueur which has inspired others flavoured with coffee or chocolate.

Bénédictine D.O.M.: A brandy based liqueur flavoured with 27 herbs and spices, originally made by Benedictine monks from Fécamp, Normandy, France, in 1510. The monks considered this liqueur to be one of God's greater glories (D.O.M. stands for *Deo Optimo Maximo*, to God most good, most great). The secret ingredients were lost after the Revolution in 1789 but were rediscovered in the 1860s when production restarted. Still made in Fécamp.

B&B: A blend of Bénédictine and Brandy. Drier than Bénédictine.

Calisay: A herb liqueur with a brandy base from Catalonia, with a slightly bitter after taste from its cinchona bark (quinine) flavouring.

Chambord: A black raspberry liqueur from the Loire Valley, France. Extracts of black raspberries and blackcurrants blended with a blackberry and raspberry infusion are added to cognac, together with vanilla extract and herbs.

Chartreuse: Made by distilling brandy with over 130 herbs and spices, this liqueur was created by the Carthusian monks of the Grande Chartreuse monastery near Grenoble in the 16th century. It is still made by the monks at nearby Voiron despite their having been expelled twice from France, firstly with the Revolution, returning after the defeat of Napoleon, then again in 1903 when they started production in Tarragona, Spain. It was re-established in France in 1932 when they finally returned but continued in Tarragona also until 1991.

Aged in cask for up to five years before bottling. There are two varieties: Green Chartreuse, naturally coloured by the chlorophyll in the herbs, is the stronger; Yellow Chartreuse, coloured with saffron, is weaker and sweeter.

Cherry Brandy: An infusion of cherries, with some of their kernels, in brandy. Invented by Thomas Grant of Kent in 1774, using black morello cherries. Most is now made in Holland.

Cointreau: A colourless orange-flavoured liqueur of the Curaçao family, produced in Angers, France, since 1849. (*See* **Curaçao**).

Crème de . . . : A group of liqueurs named after their flavouring agent, which is usually fruit. They are made by macerating the flavouring in neutral-tasting unaged brandy which is then filtered, sweetened, and sometimes has colouring added. The resulting liquid is not aged and generally has a lower alcoholic strength than the more traditional liqueurs. Popular in cocktails.

Mostly French, some Dutch, the most common are: *Amande* (almond); *Ananas* (pineapple); *Banane* (banana); *Cacao* (from cocoa beans and vanilla, can be brown or colourless); *Cassis* (blackcurrant, originally from Dijon, France); *Fraise/Fraise des Bois* (strawberry, wild strawberry); *Framboise* (raspberry); *Mandarine* (tangerine); *Menthe* (peppermint, green or colourless); *Mûre* (blackberry); *Myrtille* (bilberry); *Noix* (walnut, from Gascony); *Noyau* ('fruit stone', from peach and apricot stones); *Pêche* (peach); *Prunelle* (sloe); *Rose* (rose petals); *Violette* (violets).

Curaçao: Invented by the Dutch using white rum, now made from brandy. This is infused with the dried peel of bitter green oranges from the island of Curaçao in the West Indies. Distillation produces the colourless *triple sec*; this can then be coloured and sweetened to make *Blue Curaçao*, to which Valencia orange peel is added, and *Orange Curaçao*, with added bitters.

Cuarenta y Tres: Made in Cartagena, Spain, since 1924, from a brandy base infused with herbs. The name, forty three, refers to the number of ingredients.

Drambuie: A sweet, golden liqueur made from a mix of Scotch malt and grain whiskies flavoured with herbs and heather honey. Its name is from the Gaelic *An Dram buidheach*, the drink that satisfies. Said to have been a restorative for Bonnie Prince Charlie but not made commercially until 1906. Now made near Edinburgh.

Elixir d'Anvers: A yellow bitter-sweet liqueur from herbs and seeds, made in Antwerp. Invented in 1863.

Forbidden Fruit Liqueur: An American liqueur made from grapefruit with honey and orange in a cognac base.

Frangelico: From Piedmont, Italy, this straw-coloured liqueur is made from hazelnuts, berries and herbs. Its name, from Fra Angelico, shows its monastic origins.

Galliano: A golden coloured liqueur flavoured with liquorice, aniseed, herbs and vanilla, produced in Milan, Italy. Named after a Major in the Italian-Abyssinian war in 1896.

Glayva: A Scotch whisky liqueur flavoured with herbs, honey and orange peel invented mid-19th century. Made near Edinburgh.

Goldwasser: Named from the edible gold flakes in the bottle, this caraway and aniseed flavour liqueur was created in Danzig (Gdansk) in 1598, based on *Kümmel*. Now produced in Berlin.

Grand Marnier: Similar to curaçao but with a base of the highest quality cognac, then aged. French, invented in 1880. (*See* **Curaçao**)

Izarra: A herb liqueur with an armagnac base made in Bayonne. A Basque version of chartreuse, it also comes in a stronger green and a yellow version. The name is Basque for "the star".

Jägermeister: Made in Wolfenbüttel, Germany, from 56 herbs and spices and aged for one year in oak barrels. The name, "master hunter", refers to Saint Hubertus, the patron saint of hunters.

Kahlua: Mexican rich brown liqueur made from sugar cane molasses and coffee beans with vanilla and caramel. Now also made in Europe.

Kümmel: A highly digestive colourless liqueur made by distilling grain spirit with caraway seeds, fennel, cumin, orris root and other herbs. Originating in Holland in 1575, it was taken to Russia by Peter the Great and its chief centre of production in the 19th century was Riga, Latvia. Some was also made in Danzig and was the origin of *Goldwasser*. It is now made in many European countries and the USA.

Limoncello: Made from the zest of lemons and bright yellow, traditionally served ice-cold. Originally from southern Italy but now universal.

Malibu: A Caribbean liqueur made from white rum and coconut.

Mandarine: A French liqueur made by macerating mandarin oranges (tangerines) in cognac. Carotene is added to give a vivid yellowy orange colour then it is aged for several months. Invented by a Belgian in 1892.

Maraschino: A colourless liqueur from Italy made from sour cherries and their crushed stones.

Noix de coco: A coconut-flavoured rum liqueur.

Parfait Amour: Violet coloured and very sweet, from citrus fruits and spices, and subtly scented with violets. Dutch in origin, now also made in France.

Peach Brandy: An infusion of peaches in brandy, usually from France or Holland.

Poire William: Crushed pears infused in brandy, sometimes with a whole pear, achieved by attaching the bottle to the tree for the pear to grow into it. Not to be confused with the fruit brandy, Poire Williams.

Royal Mint Chocolate Liqueur: Created in 1966, this sweet and creamy liqueur has the flavour of an after dinner mint.

Sambuca: An Italian aniseed liqueur flavoured also with elderberries, from which it derives its name (*sambucus nigra*).

Sloe Gin: Made by infusing sloe berries in gin, the deep red liqueur is then matured in wood for several years.

Strega: A yellow liqueur of complex flavours from its use of over 70 herbs including mint and fennel, made in Benevento, Italy, since 1860. The name means "witch".

Tia Maria: A deep brown liqueur of 5-year-old Jamaican rum flavoured with Blue Mountain coffee and spices.

Triple Sec: A colourless curaçao. *See* **Curaçao**.

Van Der Hum: A pale gold South African liqueur, similar to curaçao, from cape brandy and and the *naartje* tangerine. Named Van der Hum ("What's his name") by the Dutch settlers who could not remember who had invented it.

Vieille Cure: A golden liqueur from 50 herbs this is similar to Bénédictine but with a base of both cognac and armagnac. It was made by monks at Cenon in Bordeaux, France, until 1986. The name means "the old vicarage".

ANISEED BASED DRINKS

There is also a family of aniseed based drinks which does not fall readily into the classification of either liqueur or spirit. Most are drunk diluted with water. They include the French *Absinthe* (declared illegal there in 1915), *Pastis* and *Pernod*, the Greek *Ouzo* and the Turkish *Raki*.

V. SPECIAL TOPIC: COFFEE AND TEA

THE HISTORY OF COFFEE

Coffee is currently drunk by about one third of the world's people in quantities larger than those of any other drink. The name may be derived from the Arabic *qahwah*, but more plausibly perhaps from Kefa, a province of south-western Ethiopia from where the wild coffee plant was taken to southern Arabia for cultivation in the fifteenth century. The actual discovery of coffee is shrouded in legend, of which one is that it was revealed to the prophet Mohammed by the Archangel Gabriel. The most popular is that an Arab goatherd, Kaldi, who had been bemused by the unusual behaviour of his flock after the goats had eaten the berries of a particular wild evergreen bush, sampled them for himself in about A.D. 850 and was so stimulated by the experience that he told everybody about his discovery! Although the detail is obviously legendary, the broad outline may not be far from the truth.

Coffee was grown almost exclusively in Yemen until the end of the seventeenth century, and coffee has always been prized, and sometimes condemned, for its stimulating properties which are attributable to the alkaloid, caffeine, found in the green coffee bean.

The Spread of Coffee Drinking

There were attempts by the orthodox in the Islamic world to ban the drinking of coffee particularly during long religious ceremonies because of its stimulating qualities, but they were to no avail and the habit spread rapidly amongst the Arabs and on to their neighbours. It was in the Middle East of the sixteenth century that the coffee house first appeared as a focus for commerce and gossip. Coffee was introduced to Europe in the sixteenth and seventeenth centuries, where again there were some unsuccessful attempts to suppress it. When Pope Clement VIII was asked by Vatican officials at the beginning of the seventeenth century to ban coffee as the notorious drink of the Ottoman Empire, he countered the request by finding it delicious and declaring: "We shall fool Satan by baptising it". His approval was generally shared and its use spread rapidly from one country to another, with the first London coffee house being opened in about 1652.

They became similarly popular in continental Europe and in such American cities as Boston, New York and Philadelphia. The French philosophers, Voltaire and Rousseau, were habitués of *Le Procope*, one of the first coffee houses in Paris, in the eighteenth century, and Johann Sebastian Bach maintained in his *Kaffeekantate* of 1732 that "coffee was lovelier than a thousand kisses". Nevertheless not all coffee house activities were so innocuous—some had rooms set aside for duelling. It was the London coffee houses, however, which became the most famous as centres in which to exchange literary, philosophical and political ideas and in due course to conduct business.

The Café

The first recorded use of the word "café" in English to mean a "coffee house" was in 1816, but coffee lost some of its fashionable allure in the nineteenth century, although it was not until the 1880s that tea became the favoured drink of the majority in Britain and some other parts of northern Europe. The tea shop replaced the coffee house although coffee continued to be drunk in considerable quantities in some circles. Nevertheless, for many Britons the only known form of coffee was "camp coffee"—a black liquid bought in a bottle and then diluted with hot water. In the twentieth century, coffee was missed intensely during the Second World War and its aftermath. Germany tried to cope by substituting acorns for coffee beans—the notorious *Ersatz* coffee. A less extreme approach which is still favoured by some, and actually dates from 1769, is to mix powdered wild chicory root in with the coffee. Even in the western Europe of the late 1940s and early 1950s, coffee smuggling was a highly lucrative and highly dangerous activity.

As is discussed later, such coffee houses have returned to Britain but in the form of the international chain, which stands in marked contrast both to the earlier neighbourhood coffee house and to the combined house and cake shop which remains common in continental Europe and for which Vienna is probably the uncrowned capital.

It must also be remembered that coffee is used not only as a drink but as a flavouring for many desserts and ice creams, and also as the basis for several popular liqueurs including Kahlua and Tia Maria.

The Cultivation of Coffee

The demand for coffee soon led to the plant's cultivation spreading from the Yemen to Indonesia, then the Dutch East Indies, in the seventeenth century, and to the Americas in the eighteenth. The largest focus of production by the late nineteenth century was Brazil. There are some 25 species of the coffee plant but only two are normally cultivated, *coffee arabica* and *coffea canephora*, the latter usually being of the robusta variety. The *arabica* was the first species to be identified and cultivated and is deemed the more aromatic and flavourful. It is grown principally nowadays in Central and South America, the Caribbean and Indonesia.

Most coffees are in practice blends but mild coffees must be made from the quality varieties of *arabica* grown in Central and South America excluding Brazil. The many types of Brazilian *arabica* coffee are considered less refined in taste and aroma. Coffees from Cameroon, Ethiopia, Kenya and Tanzania are varieties related to the mild variety of *arabica*. The robusta variety of *coffea canephora*, which is grown mainly in Africa and Vietnam, is cheaper and has traditionally been less esteemed, but it is stronger and more resistant to disease, more fruit-bearing and more adaptable to warm, humid conditions than any of the *arabica* varieties. It is much used to make instant coffee, a process which was only perfected in the 1950s. The concentration of caffeine in *arabica* varieties ranges from 0·8–1·5% and in robusta from 1·6–2·5%.

The Processing of Coffee

The wild coffee plant is an evergreen bush, some 8–10 metres high, bearing a fruit 15–18mm long known as a cherry and red when ripe. The cherry comprises a fleshy pulp and two seeds.

With cultivated coffee, those seeds are separated from the pulp and dried to reduce the water content from 65–70% by weight to 12–13%. In the case of most *arabica* coffees, this is achieved by a wet process involving fermentation of the unwanted pulp, and in the case of Brazilians and robustas by a dry process using sunlight or hot air driers. The resulting beans are then graded in accordance with national practice in the absence of any internationally recognised grading standards. Beans produced in humid regions must be exported rapidly to avoid the danger of mould or parasite infection.

The beans are subsequently roasted at a temperature rising to about 220°–230°C (430°–440°F) which reduces their weight by between 14% and 23% but expands their size by between 30% and 100%. It is at this stage that the characteristic aroma of coffee appears.

The final grinding may be performed by the consumer at home or by the manufacturer industrially followed by the essential packaging of the coffee in hermetically sealed containers to prevent oxidation.

Styles of Coffee

The French diplomat, Talleyrand, maintained that the perfect cup of coffee should be "black as the devil, hot as hell, pure as an angel and sweet as love". Not all would agree and a remarkable range of styles of coffee and coffee-making has evolved to meet changing tastes and circumstances. Some of the more commonly encountered are:

Americano: strong black coffee produced in a coffee machine.

decaffeinated: The beans have been steamed and the increased moisture content has brought the caffeine to their surface. They have then been washed with an organic solvent which is itself steamed off prior to final drying of the bean. Particularly suitable for coffees served late when the stimulus of the caffeine could prevent sleep.

espresso: the famous Italian style created by forcing pressurised boiled water through finely ground coffee in a machine. The resulting drink is highly flavoured with little bitterness because the water has had little contact with the grounds. The following are variations on *espresso*:

- *cappuccino*: an *espresso* coffee with hot milk topped with frothed milk and usually dusted with chocolate powder. Named after the white cowl of the Capuchin friars. It first originated as "*kapuziner*" in the 1700s in Viennese coffee houses.
- *corretto*: a shot of *espresso* "corrected" with a shot of brandy, sambuca or grappa.
- *latte*: a shot of *espresso* topped with hot steamed milk, sometimes covered with steamed froth but with less than for a *cappuccino*.
- *macchiato*: "stained" or "marked" with a little milk.
- *marocchino*: made with a dash of milk and cocoa powder.
- *(ri)stretto*: made with less water and thus stronger.

filter: the hot water is filtered through the coffee using a filter (paper) and drips into a jug below. It is never recirculated.

instant (or **soluble**): a liquid concentration of coffee has been prepared with hot water and then dehydrated either by spray drying in hot air, by drying under vacuum or by freeze-drying. Hot water is added by the consumer to the soluble granules or powder to create reconstituted instant coffee.

Irish: after-dinner coffee to which Irish whiskey has been added.

percolator: the water is boiled in the percolator and led up to the internal coffee holder by means of a tube whereafter it drips back into the percolator. The process is repeated until the desired strength is reached.

Turkish (known in some countries as Arab or Greek): Finely ground coffee from Mocha (Al-Mukha) in the Yemen and sugar are thrice-boiled in a small metal coffee maker. Traditionally served in very small cups with a large glass of water.

The Renaissance of the Coffee House

As noted earlier, the British coffee house was eclipsed during the nineteenth century by the more fashionable tea shop. Its return to favour can perhaps be dated to the "swinging sixties" when young people and specially students flocked to a new kind of themed coffee shop, of which *Le Macabre* in London's Soho was a particularly well-known example. The coffee was increasingly Italian in style. Most of these independent shops or coffee bars did not last, however, and the real change came with the arrival of the mass-market coffee-shop chain of which *Starbucks* is the exemplar. Founded as a single shop in Seattle, USA, in 1971, it had expanded to 1300 shops by 1997 and to 9000 worldwide by 2005. That expansion did, however, underline the very real differences between the new style of coffee shop chain, which includes such familiar names as *Costa* (now the UK's largest), *Caffè Nero* and *Coffee Republic* as well as *Starbucks*, and the earlier neighbourhood shop. Its ownership, operations and financing are international and the chain has the volatility and vulnerability of modern big business as a whole. *Starbucks* virtually collapsed in 2007 before a rebound which raised profits to their highest ever level in the third quarter of 2010. The coffee shop market as a whole was worth £5 billion in 2010, but the cost of the actual coffee in the cup is barely 5 % of the shop price. Advertising and image are all-important.

There are other significant differences between the contemporary chain shop, of which there are more in the UK than anywhere in Europe, and the earlier coffee shop. They are places of quick refreshment and of general socialising but rarely of business or of philosophical or political discussion. The wheel though may come full circle. Booksellers such as *Foyles* and *Waterstones* regularly include what are primarily coffee houses on their premises. Perhaps the proximity of books will regenerate the fashion for literary discussion also.

THE STORY OF TEA

Tea is now a commonplace drink in most of the world but for many centuries it was unknown outside China. It was first discovered, according to legend, by the emperor Shen Nung in the third millennium B.C., when a leaf from the wild tea tree he was sitting under fell into water being boiled for him to drink and he found the resulting infusion to be pleasantly reviving. Although its true origin is necessarily uncertain, there are early accounts in China of its use as a medicine or a stimulant, and in the first centuries A.D. as a beverage. At that time the leaves were compressed into cakes which were baked then pounded into pieces before boiling water was added. The first account of methods of tea cultivation, processing, and drinking dates from the 3rd century A.D. and tea has been found in tombs of the Han Dynasty (206 B.C.–A.D. 220), one container being clearly labelled with the Chinese character for tea, *ch'a*. By the time of the Tang Dynasty (A.D. 618–906) tea had become the national drink of China.

By the 9th century tea drinking had spread from China to Japan, where it became an important social ritual. In the Japanese tea ceremony, boiling water was poured on to powdered tea and then whisked. It had also spread into Tibet, where it was mixed with butter. It was not until 1606, however, that Dutch traders imported it to Europe, and the earliest record of it in Britain is from an advertisement of 1658 for "Tay alias Tee" in a London coffee house. Then in 1662 came the trigger for its rising popularity: when Catherine of Braganza came from Portugal to marry Charles II her dowry included a chest of tea. It started a fashion at court which spread to the middle classes. The East India Company, which held the monopoly of British trade with the "Indies", brought in the first 100 lbs of China tea from Java in 1664.

The Tea Garden

In the 17th century, tea was drunk in coffee houses, largely by men and invariably with sugar. With the opening of "tea gardens" in the 18th century, of which the most famous was Vauxhall, in London, it became popular with women also. Thomas Twining set up "Tom's Coffee House" in 1706, soon specialising in tea and given the Royal Warrant for it in 1711, which the company still holds. The rise in demand for tea was phenomenal and it was more popular in Britain than any other European country. Initially it was sold by apothecaries and milliners. Consumption increased over the century from 100,000 lbs to 23 million lbs. Tea was, however, costly and highly taxed so smuggling was rife until in 1784 William Pitt the Younger reduced the tax from 119 % to 12½ %, which virtually stopped smuggling.

Tea Production in India

Although by 1830 there were 30 million lbs imported from China, there were doubts over the reliability of Chinese exports and when the East India Company's monopoly of trade with China ended in 1834 it started its own plantations in India, specifically in Assam, using native labour and, initially, seeds from China. Production there was so successful that by 1888 the amount of tea imported to Britain from India had overtaken that from China. From 1867 it was grown also in Ceylon, where 15 % of the estates were bought by Sir Thomas Lipton in 1890. By 1900 Ceylon was exporting 150 million lbs of tea, mainly to Britain, and India was producing almost 200 million lbs, 85 % of which was exported to Britain. After India and Ceylon became independent in the 1940s, production spread to Kenya.

The demand for fresh tea led to the development of the rapid tea clippers, of which the most famous was the *Cutty Sark*, launched in 1869.

Today, India is the world's largest producer, followed by China, but due to domestic consumption, Sri Lanka (Ceylon) and then Kenya are the largest exporters. In Britain, most tea is sold in teabags, an accidental invention in America in 1908, when tea samples were sent out in silk bags.

The Rise of the Teashop

Despite tea's immense popularity it did not displace coffee as the preferred non-alcoholic drink before the advent of the tearoom in the 1880s, of which the first, allegedly, was at the ABC (Aerated Bread Company) bakery shop at London Bridge station. This was so successful that ABC had opened over 50 more by 1890, soon to be followed by, among others, Lyons on Piccadilly in 1894. By 1900 there were 250 Lyons Tea Shops with their distinctive white and gold decor, fulfilling a need for inexpensive, clean and respectable places for ladies and their children to eat and drink tea. Grander tearooms were found in expensive hotels, with palm courts and tea dances. In Glasgow Charles Rennie Mackintosh designed the elegant Willow Tea Rooms in 1903, and in 1919 the first of today's popular Bettys Café Tea Rooms opened in Harrogate.

Tea and Politics

Unlikely as it may seem for such an innocuous drink, tea has at times played a significant role in world politics, particularly those of the British Empire. Anger at Britain's duty on imported tea led to the "Boston Tea Party" of 1773 when a cargo was tipped overboard in protest, and contributed to the American War of Independence. The ultra-Republicans of today are the "Tea Party". The Opium War of 1840–42 between Britain and China, which made Hong Kong British, occurred when China tried to ban the imports of opium from British India which were paying for Britain's tea. The terrible conditions of workers on the tea plantations of Assam contributed to the rejection of British rule which culminated in Indian independence in 1947. In Ceylon the workers were mainly Tamil immigrants from south India, of whom there were 300,000 by 1900. The tensions between the native Sinhalese and the Tamils ultimately led to the civil war, 1983–2009. British governments treated tea as an "essential" for public morale in both World Wars.

The Cultivation of Tea

Tea is made from the dried leaves of an evergreen tree which is a species of camellia, *Camellia sinensis*, and of which there are two main varieties: *sinensis*, native to China, and *assamica*, native to Assam in India and South-East Asia. Although the tree can grow to over 40 feet, for tea production it must be pruned to a small bush. It grows best in hot, humid conditions with some 100 inches of rain a year, and as a cooler temperature at night produces a better flavoured tea, most is grown on high land in the tropics.

Leaves are harvested from tender new shoots only, plucking no more than two leaves and a bud. The leaves are dried then roasted, after which they are formed into balls and rolled to expel moisture and curl the leaves before a final roasting. Dust is removed by sieving and the leaf is sorted into grades ready for packing in airtight containers.

Green, Black, and White

Initially all tea in China was green, black tea not being produced until the Ming dynasty (1368–1644).

It was green teas which first found their way to the west but black soon followed. It was wrongly thought until 1843 that green and black came from different varieties of tea plant.

To produce green tea, the natural fermentation of the leaves, which starts as soon as they have been picked, must be halted as soon as possible, by either steaming or mild roasting. For black tea, fermentation is encouraged: the leaves are left for several hours then beaten by hand to release the enzymes which brown the leaves. The final roasting is then done at a higher heat to totally blacken the leaves. Teas such as *oolong* and *pouchong* are half-way between green and black, having been allowed to only half ferment before being roasted. White tea, named from the silvery white hairs on the buds which alone constitute the best quality, is the least processed - not rolled and only slightly oxidised.

Initially most tea drunk in Britain was green but by the end of the 18th century black tea had become more popular. This increased the use of milk, which had not previously been common. This change was no doubt in part due to concern at the then use of poisonous copper dyes to augment the colour of green teas. Eventually black teas dominated western taste, but more recently there has been a resurgence of interest in green teas which are seen as having more health benefits.

White teas, with more nutrients and less caffeine, are an even more recent import to interest the health-conscious.

Classification and Types of Tea

Teas are classified first by degree of fermentation, second by geographical region, and third, now only for loose teas, by description of the leaf: *Orange Pekoe* (long and thin), *Pekoe* (shorter and thin) and *Souchong* (broad); these are all prefixed by *Broken* for broken leaves and by *Flowery* if a high proportion of buds.

In addition to these general classifications, there are names for special types of tea. These include:

Earl Grey: A black, traditionally China, tea flavoured with oil of bergamot. Allegedly copied from a blend given to the 2nd Earl Grey, prime minister at the time of the abolition of slavery in the British Empire. Normally drunk without milk.

Gunpowder: A superior tightly rolled small leaf green tea. An original category of China tea named from its resemblance to lead shot.

Jasmine: Green China tea scented with jasmine flowers.

Lapsang Souchong: A smoky black tea from leaves smoked over pine wood. *Souchong* relates to an original category of China tea, denoting a superior quality black tea. Drunk weak without milk.

Russian Caravan: Strong black China tea with a smoky aroma.

Twankay: An old grade of green China tea from wild or semi-wild bushes. Popular in London mid-19th century, it gave rise to the name of the dame in the panto Aladdin, Widow Twankey.

SPORTING ALMANAC

This section provides a wide-ranging variety of tables giving numerous recent winners of major popular sporting competitions, both domestic and international. The results included here range from cricket to football and from the University Boat Race to the Epsom Derby and the Grand National.

* Lewis Hamilton became the first British driver in history to successfully defend his Formula One crown.

Note: In the May 2016 Spanish Grand Prix, the Dutchman Max Verstappen made history by becoming the youngest-ever driver to win a F1 race (aged 18 years and 228 days).

ROWING

THE UNIVERSITY BOAT RACE

The Boat Race is run over 4 miles 374 yards. The record time is held by Cambridge (16 min., 19 secs in 1998). The first race was rowed in 1829 and was won by Oxford at Henley-on-Thames. In 2015, the women's race, which began in 1927, was run for the first time over the same course as the men. Oxford were the winners.

* The competition was the Five Nations Championship prior to 2000. A bonus points system was introduced in 2017.

Wins and shared wins since Championship began in 1883:

England 38 Wales 37 France 25 Scotland 22 Ireland 21

Grand Slam Winners:

England	13
Wales	11
France	9
Scotland	3
Ireland	2

Triple Crown Winners:

England	25
Wales	22
Scotland	10
Ireland	10

THE WORLD OF SCIENCE

A wide-ranging picture of scientific discovery, designed to explain some of the most important concepts in cosmology, physics, chemistry, biology, genetics and the story of human evolution. It also aims to give some account of major developments in astronomy, from extra-solar planets to massive black holes and major space missions. Also included is a variety of useful scientific tables. Readers will find many definitions of scientific terms in the General Information section. For the history and geology of our planet, see Section V.

TABLE OF CONTENTS

I. **Astronomy—Understanding the Cosmos** **3–9**
Looking at the Universe 3
Planets, Stars and Galaxies 3
The Origin, Evolution and Ultimate Fate of the Universe 6

II. **Physics—the Fundamental Science of Matter** **10–22**
What Physics is about 10
Particles and Forces 10
Some Members of the Atomic Family 16
Quantum Theory and Relativity 17

Periodic Table 57
Measures, Units and Metrology 58

THE WORLD OF SCIENCE

In Parts I, II, and III the inanimate universe is described. This is the world of astronomy, space research, physics, and chemistry. There are already many interesting links which join this realm to that of the living and make it difficult to say where the boundary lies. Nevertheless it is still convenient to accord biological science and human evolution two separate chapters, IV and V. Part VI provides some useful scientific tables.

I. ASTRONOMY—UNDERSTANDING THE COSMOS

LOOKING AT THE UNIVERSE

Introduction

We can observe the universe in many different ways. First, there are waves of visible light together with invisible rays of somewhat longer (infra-red) and somewhat shorter (ultra-violet) wavelengths. These waves show us the bright astronomical objects and, to make use of them, astronomers have constructed telescopes of great power and precision backed up with cameras, spectroscopes, and numerous auxiliaries. The biggest telescope in the world is the 10 m reflector based at Mauna Kea in the United States. The earth's atmosphere acts as a distorting and only partially transparent curtain and the erection of telescopes on satellites is beginning to extend optical telescope performance significantly. Indeed, the Hubble Space Telescope, launched back in 1990, has dramatically expanded our knowledge of the universe.

Secondly, there are radio waves of much longer wavelength than light. Radio telescopes are sensitive radio receivers with specialised aerial systems. The scientific stature of modern radio astronomy was first emphasised by the award back in 1974 of the Nobel Physics Prize to two Cambridge radio astronomers, Ryle and Hewish.

Other types of radiation reach the earth from outer space but do not necessarily penetrate the atmosphere. With the advent of satellite-borne detectors, mountain-top telescopes of increasing sophistication and apparatus buried in deep mines, new facets of X-ray, gamma-ray, optical UV and infrared astronomy are now rapidly deepening our knowledge of the nature of the universe and of the violent processes by which galaxies as well as individual stars and planetary systems evolve.

Gravitational Wave Astronomy

Currently, a new area of astronomy called gravitational wave astronomy is being researched. It is predicted by Einstein's general theory of relativity and measures the wobble in space-time caused as massive bodies are accelerated or disturbed.

Vast Distances and Large Numbers

To visualise the huge scale of the universe is almost as much a problem for the scientist as for the layman. The conventional shorthand is to express 1,000 as 10^3; 1,000,000 as 10^6. On this scale the earth is $1{\cdot}496 \times 10^8$ km away from the sun.

These distances are minute by comparison with the distance even to the nearest star, Proxima Centauri, some 4×10^{13} km away. This distance is more conveniently expressed in terms of the travel time of light itself. With a velocity of nearly 300,000 km per second, in a year light travels about $9{\cdot}46 \times 10^{12}$ km. The distance to Proxima Centauri is therefore 4·2 light years.

Even this distance, enormous on our terrestrial scale, is a small cosmic distance. The diameter of our Galaxy is about 10^5 light years, while the most distant objects yet observed lie over $1{\cdot}3 \times 10^{10}$ light years away. In 2015 scientists found a protogalaxy that is 13·42 billion light years away. Some astronomical distances are shown on **T8**.

PLANETS, STARS AND GALAXIES

The Solar System

The earth is the third, counting outward, of the planets revolving in nearly circular orbits round the sun. Some of their particulars are given in the Table (**T8**). The sun and its planets are the main bodies of the solar system. Mainly between the orbits of Mars and Jupiter revolve numerous small bodies—the dwarf planets and asteroids, the largest of which, Ceres, is only 947 km in diameter.

Apart from these, the solar system is tenuously populated with particles varying in size from about a micron (10^{-6} m) to hundreds of metres in diameter. Some of these objects collide with the earth's atmosphere. The smaller particles (micrometeoroids) are too small to be visible. Larger particles (meteoroids) cause the phenomenon known as meteors (commonly referred to as 'shooting stars') when they burn up at around 100 km altitude. The particle collides with air molecules. This causes frictional heating which usually results in complete vapourization of the particle. Even larger chunks, of rocky or iron composition, cause the rare and brilliant fireballs, some of which survive their high-speed flight through the earth's atmosphere and may later be recovered. Such objects (meteorites) are very important, providing examples of extraterrestrial rocks, and thus giving the composition of some of the most primitive material left in the solar system. Collisions with very large meteorites are now very rare.

The large meteorite crater in Arizona is one recent reminder that such collisions still occur, although much less frequently now. The surfaces of Mercury, the Moon, Mars, and Venus together with those of many other planetary satellites still show the scars from collisions with a multitude of objects of up to tens of km in diameter.

Comets

Comets are fascinating objects which, from time to time, provide a spectacular sight. Many thousands of comets have been observed so far, and scores of new ones are discovered each year. At the heart of every comet is a small nucleus. In 1986 the Giotto space probe revealed that Halley's comet has a potato- shaped nucleus measuring 15 km by 10 km. This nucleus consists of ices of various gases, chiefly water, interspersed with dust particles. In their highly elliptical orbits comets spend most of their life at great distances from the sun, where the temperature is very low because of the feeble solar radiation, so that all the "icy" materials are solid. Periodically, when each comet returns to the inner parts of the solar system, the increasing solar radiation heats the surface layers, evaporating the volatile ices, which carry the surface dust away from the comet nucleus. Solar-radiation pressure, acting on the dust constituents, and the solar wind acting on the ionised constituents, form the gigantic cometary tails which may reach 2×10^8 km in length—larger than the radius of the earth's orbit.

The dramatic impact of the fragments of Comet Shoemaker-Levy 9 on the dark side of Jupiter in 1994 created spots on the planet's surface that were as big as the earth's diameter and that lasted for seven weeks.

Scientists are increasingly convinced comets aided the creation of life on earth.

The Sun

The sun itself is a dense, roughly spherical mass of glowing matter, 1,392,000 km across. Its heat is so intense that the atoms are split into separated electrons and nuclei and matter in such a state is called plasma. At the sun's centre the temperature has the unimaginable value of about 15 million degrees Centigrade (a coal fire is about 800°C). Under such conditions the atomic nuclei frequently collide with one another at great speeds and reactions occur between them. The sun consists largely of hydrogen and, in the very hot plasma, the nuclei of hydrogen atoms interact by a series of reactions whose net result is to turn hydrogen into helium. This is a process which releases energy just as burning does, only these nuclear processes are incomparably more energetic than ordinary burning. In fact, the energy released is great enough to be the source of all the light and heat which the sun has been pouring into space for thousands of millions of years.

The Solar Wind

Emerging from the sun and streaming past the earth is a "solar wind" of fast-moving electrons and protons (**T11**) whose motion is closely linked with the behaviour of an extensive magnetic field based on the sun. In fact, the region round the sun and extending far into space past the earth is full of complex, fluctuating particle streams and magnetic fields which interact with planetary atmospheres causing, among other things, auroras and magnetic storms.

Stars

In colour, brightness, age, and size the sun is typical of many billions of other stars. Only from the human point of view is there anything special about the sun—it is near enough to give us life. Even the possession of a system of revolving planets is now routinely observed in other stars.

No star can radiate energy at the rate the sun does without undergoing internal changes in the course of time. Consequently stars evolve and old processes in them give rise to new. The exact nature of stellar evolution—so far as it is at present understood—would be too complex to describe here in any detail. It involves expansion and contraction, changes of temperature, changes of colour, and changes in chemical compositon as the nuclear processes gradually generate new chemical elements by reactions such as the conversion of hydrogen to helium, helium to neon, neon to magnesium *etc*.

The speed of evolution changes from time to time, but is in any case very slow compared with the pace of terrestrial life; nothing very dramatic may occur for hundreds of millions of years. Evidence for the various phases of evolution is therefore obtained by studying many stars, each at a different stage of its life. Thus astronomers recognise many types with charmingly descriptive names, such as supergiants, blue giants, sub-giants, red, white and brown dwarfs. Hypervelocity stars, first discovered in 2005, can travel at 2 million miles per hour.

Stellar Evolution

The path of stellar evolution may be marked by various explosive events. One of these, which occurs in sufficiently large stars, is an enormous explosion in which a substantial amount of the star is blown away into space in the form of highspeed streams of gas. For about a fortnight, such an exploding star will radiate energy 200 million times as fast as the sun. Japanese and Chinese (but not Western) astronomers recorded such an occurrence in A.D. 1054, and the exploding gases, now called the Crab nebula, can still be seen in powerful telescopes and form a cloud six or seven light-years across. While it lasts, the explosion shows up as an abnormally bright star and is called a *supernova*. In late February 1987 a spectacular supernova was observed in our nearby galaxy the Large Magellanic Cloud. At a distance of only $1{\cdot}7 \times 10^5$ light years this supernova was the closest to the Earth for over 400 years. Many theories have been confirmed by the findings.

Groups of Stars

It is not surprising that ancient peoples saw pictures in the sky. The constellations, however, are not physically connected groups of stars but just happen to be patterns visible from earth. A conspicuous exception to this is the Milky Way, which a telescope resolves into many millions of separate stars. If we could view the Milky Way from a vast distance and see it as a whole we should observe a rather flat wheel of stars with spiral arms something like the sparks of a rotating Catherine wheel. This system of stars is physically connected by gravitational forces and moves through space as a whole; it is called a *galaxy*.

The galaxy is about 10^5 light-years across and contains roughly 10^{11} stars. An inconspicuous one of these stars near the edge of the wheel is our sun; the prominent stars in our night sky are members of the galaxy that happen to be rather near us. Sirius, the brightest, is only 8·6 light-years away.

The galaxy does not contain stars only, there are also clouds of gas and dust, particularly in the plane of the galaxy. Much of the gas is hydrogen, and its detection is difficult. However, gaseous hydrogen gives out radio waves with a wavelength of 21 cm. Radio telescopes are just the instruments to receive these, and workers in Holland, America, and Australia detected the gas clouds by this means. Back in 1952 they found that the hydrogen clouds lie in the spiral arms of the galaxy, and this was some of the strongest early evidence for the spiral form.

Another important feature of the galactic scene is the weak but enormously extensive magnetic field. This is believed to have an intimate connection with the spiral structure.

Globular Clusters

Around the spiral arms, and forming part of the galaxy, are numerous globular clusters of stars. These are roughly spherical, abnormally densely packed, collections of stars with many thousands of members. Because of its form and density, a globular cluster may be assumed to have been formed in one process, not star by star. Thus all its stars are the same age. This is of great interest to astronomers, because they can study differences between stars of similar age but different sizes.

The 21cm radio waves that are given out by hydrogen also gave a startling and wholly unexpected finding. The outer reaches of our galaxy (and others) were seen to be rotating at a constant velocity. This implies that the mass is not concentrated in the centre, as might be expected, but is distributed in a large dark halo extending up to five times the radius of the visible part of the galaxy. The total mass of the Galactic halo is unknown but it is thought to contain at least ten times as much matter than the visible material in the galaxy.

Currently, astronomers are left with the rather fundamental question: what is the majority of the galaxy made of? There are presently a number of competing theories. It may be composed of compact sub-stellar material (such as brown dwarfs or neutron stars) known collectively as MACHOs or some kind of weakly interactive massive particle.

Galaxies

One might be forgiven for assuming that such a vast system as the galaxy is in fact the universe; but this is not so. In the constellation of Andromeda is a famous object which, on close examination, turns out to be another galaxy of size and structure similar to our own. Its distance is given in the table (**T8**). The Andromeda galaxy is the same basic structure as our own, but roughly half as big again. The Milky Way, the Andromeda nebula, and about two dozen other galaxies form a cluster of galaxies called the Local Group. It is indeed a fact that the universe is populated with *groups*, *clusters* and *superclusters*, of *galaxies*. A cluster may contain two or three galaxies, but some contain thousands.

By about 1920 it was known that there were at least half a million galaxies, and with the advent of the 2·54 m. Mt. Wilson telescope this number rose to 10^8. We now know that there are countless billions of galaxies, perhaps even two trillion.

Through the powerful telescopes the nearer galaxies reveal their inner structures. Photographs of galaxies are among the most beautiful and fascinating photographs ever taken.

Most galaxies have a spiral or elliptical structure but about 2 per cent have peculiar wisps and appendages. Some galaxies are strong emitters of radio waves. Another type of galaxy is the starburst galaxy. This is an otherwise normal galaxy in which huge numbers of stars are forming in a small volume at its centre. It is now known that there are super-massive black holes at the centre of galaxies which play a vital part in their evolution.

Rather alarmingly there is an increasingly large amount of information from observations of groups and superclusters of galaxies that they contain significant amounts of dark matter. In a similar way that the mass of the Sun can be calculated by the orbits of the planets, the mass of a galactic group can be found by observing the orbits of galactic members. By observing the galaxies and applying well understood Newtonian mechanics the mass of many clusters has been found.

There seems to be an even larger proportion of dark matter than that found in lone galaxies. This implies that the entire universe is mostly composed of dark matter interacting with ordinary matter only though the force of gravity. Currently there are a large number of major international dark matter experiments trying, quite simply, to discover what the universe is made of. In 2016 scientists discovered the galaxy Dragonfly 44,330 million light years away, which is 99.99% dark matter.

The Expanding Universe

Two discoveries about galaxies are of the utmost importance. One is that, by and large, clusters of galaxies are uniformly distributed through the universe. The other is that the distant galaxies are receding from us.

How is this known? Many readers may be familiar with the Doppler effect first discovered in 1842. Suppose a stationary body emits waves of any kind and we measure their wavelength, finding it to be L cm. Now suppose the body approaches us; the waves are thereby crowded together in the intervening space and the wavelength appears less than L; if the body recedes the wavelength appears greater than L. The Austrian physicist, J. Doppler (1803–53), discovered the well-known change of pitch of a train whistle as it approaches and passes us. The same principle applies to the light. Every atom emits light of definite wavelengths which appear in a spectroscope as a series of coloured lines—a different series for each atom. If the atom is in a receding body all the lines have slightly longer wavelengths than usual, and the amount of the change depends uniquely on the speed. Longer wavelengths mean that the light is redder than usual, so that a light from a receding body shows a "red shift." The speed of recession can be calculated from the amount of red shift.

Hubble's Law

It was the American astronomer, V. M. Slipher, who first showed (in 1914) that some galaxies emitted light with a red shift. In the 1920s and 1930s the famous astronomer E. Hubble (1889–1953) measured both the distances and red shift of many galaxies and proved what is now known as Hubble's Law about which there is now some controversy. This states that the speed of recession of galaxies is proportional to their distance from us. This does not apply to our neighbours in the Local Group, we and they are keeping together. Hubble's Law has been tested and found to hold for the farthest detectable galaxies; they are about 7×10^9 light-years away and are receding with a speed approaching that of light.

The expansion of the universe does not imply that the Local Group is the centre of the universe—from any other viewpoint in the universe Hubble's Law would also be valid, and the distant galaxies would, similarly, all appear to be rapidly receding.

The Big Bang Theory and the Cosmic Dawn

One possible implication of this most exciting scientific discovery is that, if the galaxies have always been receding, at an early time they must have been closer together. We can calculate that about 10^{10} years ago all the matter of the universe could have been densely packed.

This is called the big bang theory (*See* **L15**). The first 100 million years after the Big Bang, when there was a vast black fog of widely spaced hydrogen atoms, is called the Cosmic Dawn. The central questions of cosmology now concern the ultimate fate of the universe, its size, age and composition. Telescopes of ever increasing sophistication on the Earth and in space are beginning to address these fundamental questions.

Quasars and Pulsars

In November 1962 Australian radio astronomers located a strong radio emitter with sufficient precision for the Mt. Palomar optical astronomers to identify it on photographs and examine the nature of its light. The red shift was so great that the object must be exceedingly distant; on the other hand it looked star-like, much smaller than a galaxy. By the beginning of 1967 over a hundred of these objects had been discovered and other characteristics established, such as strong ultraviolet radiation and inconstancy, in some cases, of the rate at which radiation is emitted. Not all of these so-called quasars are strong radio emitters; some show all the other characteristics except radio emission. It has been estimated that the "quiet" kind are about a hundred times more numerous than the radio kind. One great problem here is: how can such relatively small objects generate such inconceivably great amounts of energy that they appear bright at such huge distances? Recent observations suggest that quasars are only the central visible part of an otherwise undetected galaxy. There may also be a massive black hole near the quasar centre.

Late in 1967, while investigating quasars, Cambridge radio astronomers discovered pulsars, a new type of heavenly body. Their characteristic is the emission of regular pulses of radio waves every second or so. A pulsar in the Crab nebula has a repetition rate even faster—about 1/30 sec—and it follows that pulsars must be very small bodies little if at all bigger than the Earth.

White Dwarfs and Neutron Stars

The existence of such small bodies raises again the problem of the ultimate fate of evolving stars. Much depends on their mass because this determines how strong the inward pull of gravity is. For a star to be at least temporarily stable the inward pull must be balanced by an outward pressure. In the sun this is the pressure of the burning hydrogen and the resulting average density is about 1·4 times that of water (**Table, T8**). In some stars the inward pressure is so great that collapse proceeds until it is balanced by a different type of outward pressure that sets in when electrons and atomic nuclei are forced into proximity.

Stars so formed are the "white dwarfs". They are millions of times denser than the sun—"a matchbox of their matter would weigh a ton"—and they are very small though not small enough to be pulsars. The latter are now generally thought to be a million times denser even than white dwarfs and to consist largely of tightly packed neutrons. They are called *neutron stars*.

Black Holes and Event Horizons

Could the tendency of a massive star to fall inwards ever be so great that no outward pressure known to physics would suffice to balance it? Apparently it could! Astrophysicists know that such a gravitational collapse creates a high density object whose gravitational field is too strong to allow anything—including light waves—ever to leave the body. Such objects are called "black holes" because, light and other signals being unable to emerge from them, their matter has literally disappeared from view.

Black holes could be detected by the disturbance their gravitational attraction causes to neighbouring visible stars and also because atoms attracted by the black hole should emit intense X-rays before falling so far in that they too disappear into the black hole. Both of these detection methods led astronomers to realise there are super massive black holes at the centre of galaxies (including our Milky Way). They are caused by hypernovae. The edge of the black hole is the *event horizon*. The theory of gravitational collapse raises profound and unresolved problems about our physical concepts.

In 2013 scientists discovered compelling evidence of the existence of the biggest black hole ever found, with a mass equivalent to 17 billion of our suns. Even larger black holes may reside elsewhere.

THE ORIGIN, EVOLUTION AND ULTIMATE FATE OF THE UNIVERSE

Scientists can only attempt to explain the universe by relating its observable structure to the features predicted by alternative theories of its origin and development. The time span of all our observations of the Cosmos is very small by comparison with the lifetime of the universe (more than 10^{10} years). Also, contrary to many other scientific disciplines, it is impossible to repeat the "experiment", under controlled conditions. We must, therefore, explore the evolution of the universe by using the fact that light from the most distant galaxies has taken about 10^{10} years to reach us, thus providing us with a crucial view of the universe at a much earlier epoch.

Models of the Universe

Several models of the universe have been based on Einstein's theory of General Relativity (**T17**). Einstein's equations may be solved to predict the evolution of the universe. However, there is a spectrum of solutions which vary from a continuous and indefinite expansion at the present rate to an eventual slowing and subsequent contraction to a dense state, again in the distant future, which hints at a "pulsating" universe.

The Formation of Galaxies and Stars

On any theory of the universe, some explanation has to be found for the existence of clusters of galaxies. In all theories galaxies condense out from dispersed masses of gas, principally hydrogen.

It is believed on theoretical grounds each galaxy could not condense into one enormous star but must form many fragments which shrink separately into clusters of stars. In these clusters many stars, perhaps hundreds or thousands or even millions, are born. A small cluster, visible to the naked eye, is the Pleiades. The Orion nebula, visible as a hazy blob of glowing gas in the sword of Orion, is the scene of much star-forming activity at present. However, the earliest evidence for witnessing the birth of a star came from observations by the Infrared Astronomical Satellite (IRAS). Deep within a gas and dust cloud called the Ophiuchus dark nebula, matter fell inward in a manner predicted by the theories of star formation. At the centre of this collapsing cloud there was an embryonic star perhaps only 30,000 years old.

The Evolutionary Theory

According to the Evolutionary theory the "initial dense state" consisted of very hot plasma in a state of overall expansion. The expanding plasma was both cooling and swirling about. The random swirling produces irregularities in the distribution of the hot gas—here it would be rather denser, there rather less dense. If a sufficiently large mass of denser gas happened to occur, then the gravitational attraction between its own particles would hold it together and maintain its permanent identity, even though the rest of the gas continued to swirl and expand. Such a large mass would gradually condense into fragments to become a cluster of galaxies.

Revolutionary Discoveries

The 1960s witnessed revolutionary developments in both observational and theoretical astronomy. For example, scientists now agree that remote sources of radio waves are more abundant the weaker their intensity. This strongly suggests that they are more abundant at greater distances. Thus the universe is not *uniform* as the original steady-state theory prescribed. Since greater distances correspond to earlier times, any extra abundance of objects observed at the greater distance means that the universe was denser in its younger days than now. This favours an evolutionary theory of the universe.

The same theory requires that the initial dense state of the universe—aptly christened "the primaeval fireball"—should contain intense electromagnetic radiation with a distribution of wavelengths characteristic of the high temperature. As the fireball, *i.e.*, the universe, expanded over a period of about 10^{10} years it cooled, and one feature of this process is that the wavelengths of the radiation increase and their distribution becomes characteristic of a much lower temperature. In fact, the wavelengths should now be concentrated round about 1 mm to 1 cm (corresponding to about −270°C) and the radiation should approach the earth uniformly from all directions. Radiation just like this was detected in the 1960s by extremely sensitive instruments both at ground-based observatories and flown from balloon payloads high in the earth's atmosphere— above most of the water vapour and other constituents which interfere with such delicate observations. This "microwave background" radiation strongly supported the evolutionary or "Big Bang" theory as opposed to the "Steady-State" theory, which cannot rationally explain the radiation.

In 1992 data from the Cosmic Background Explorer (COBE) satellite strengthened the Big Bang theory still further. Minute variations in the temperature of the background radiation across the sky help to show that the distribution of matter in the early universe could act as a blueprint for the future large-scale structures we can observe today. Back in 2003 a satellite called MAP began to re-measure the cosmic background radiation in exquisite detail.

The Formation of the Chemical Elements

A stable nucleus is one that lasts indefinitely because it is not radioactive. There are 274 known kinds of stable atomic nuclei. These nuclei are the isotopes (*q.v.*) of 81 different chemical elements; the other elements, including, for example, uranium and radium are always radioactive. Some elements are rare, others abundant. The most common ones on earth are oxygen, silicon, aluminium, and iron.

However, the earth is rather atypical. It is especially deficient in hydrogen, because the gravitational attraction of our small planet was not strong enough to prevent this very light gas from escaping into space.

It is possible to examine the chemical constituents of meteorites and to infer the composition of the sun and other stars from the spectrum of the light they emit. By such means, the conclusion has been reached that 93% of the atoms in our galaxy are hydrogen, 7% are helium; all the other elements together account for about one in a thousand atoms. A glance at the Table of Elements (*see* **T56**) will show that hydrogen and helium are two of the lightest elements: they are in fact the two simplest. The problem is to explain how the heavier chemical elements appear in the universe at all. It is here that a combination of astronomy and nuclear physics is required.

Energy

We have already referred to the fact that the energy radiated from the sun originates in nuclear reactions which turn hydrogen into helium. Why is energy given out? To answer this question we note that nuclei are made up of *protons* and *neutrons* (*q.v.*). These particles attract one another strongly—that is why a nucleus holds together. To separate the particles, energy would have to be supplied to overcome the attractive forces. This amount of energy is called *binding energy* and is a definite quantity for every kind of nucleus. Conversely, when the particles are brought together to form a nucleus the binding energy is *released* in the form of radiations and heat. Different nuclei consist of different numbers of particles, therefore the relevant quantity to consider is the *binding energy per particle.* Let us call this B. Then if elements of *high* B are formed out of those of *low* B there is a *release* of energy.

Now B is small (relatively) for light elements like lithium, helium, and carbon; it rises to a maximum for elements of middling atomic weight like iron; it falls again for really heavy elements like lead, bismuth, and uranium. Consequently, energy is released by forming middleweight elements either by the splitting up of heavy nuclei ("nuclear fission") or by the joining up of light ones ("nuclear fusion").

The Study of Fusion Processes

It is fusion that is going on in stars. The fusion processes can be studied in laboratories by using large accelerating machines to hurl nuclei at one another to make them coalesce. In stars the necessary high velocity of impact occurs because the plasma is so hot. Gradually the hydrogen is turned into helium, and helium into heavier and heavier elements. This supplies the energy that the stars radiate and simultaneously generates the chemical elements.

The Heaviest Elements

The very heavy elements present a problem. To form them from middleweight elements, energy has to be *supplied.* Since there is plenty of energy inside a star, a certain small number of heavy nuclei will indeed form, but they will continually undergo fission again under the prevailing intense conditions. How do they ever get away to form cool ordinary elements, like lead and bismuth, in the earth? One view links them with the highly explosive supernovae, to which we have already referred earlier. If the heavy elements occur in these stars the force of the explosion disperses them into cool outer space before they have time to undergo the fission that would otherwise have been their fate. The heavy elements are thus seen as the dust and debris of stellar catastrophes. The view is in line with the steady-state theory, because supernovae are always occurring and keeping up the supply of heavy elements. In the evolutionary theory some of the generation of elements is supposed to go on in the very early stages of the initial dense state and to continue in the stars that evolve in the fullness of time. It cannot be claimed that the origin of the chemical elements is completely known, but we have said enough to show that there are plausible theories. Time and more facts will choose between them.

The Formation of the Planets

Precisely how the planetary system was formed is still not understood in detail. From extremely precise observations of the movements of some nearby stars, it seems certain that other planetary systems occur among our stellar neighbours. By inference, it is thus probable that among certain classes of stars, planetary systems are very common throughout the universe.

Two other facts are crucial for any theory of planetary system formation. First, all the planetary orbits lie nearly in the plane perpendicular to the axis of rotation of the sun. The planets' rotations about the sun are all in the same direction and their axes of rotation, with two exceptions (Venus and Uranus), are close to the polar axis of their orbit planes, and in the same sense as their orbital rotation about the sun. Secondly, there is a very strong inverse correlation between planetary distance from the sun and the planet's mean density, particularly if the correct allowance is made for the effects of gravitional compression in the deep interiors of planets (greater in large than in small planets).

Rather than theories which would place planetary formation as either the random collection of pre-formed planets by the sun in its path through the galaxy or as the consequence of a very near encounter between our sun and another star, it is now generally believed that the origin of the planetary system (and most of the satellites, etc.) was a direct consequence of the process which originally formed the sun.

As the primaeval solar nebula contracted, to conserve angular momentum, its rotation rate increased, and a diffuse equatorial disk of dust and gas formed. In the cold outer region (10–20° K) of this disk, all materials except helium and possibly hydrogen could readily condense on dust particles. Near the centre the temperature was higher, increasingly so as the proto-sun heated up, initially by the energy released by its gravitational contraction and, later, by the thermonuclear processes.

The Process of Accretion

Within this rotating and swirling disk of gas and dust, the process of accretion proceeded. Low-velocity collision between dust particles from time to time allowed larger particles to be created, composed of a mixture of the heavier elements and also the "icy" materials, particularly so in the colder outer regions where more of the "ices" were in a frozen state. Virtually our only information on the composition of such particles comes from detailed study of meteorites and from spectroscopic observation of comets. Eventually rocks of the size of centimetres, metres, and even kilometres were built up in this way. The build-up, controlled by low-velocity collisions, particularly of "sticky" materials, and also by electrostatic charges, was, at all times, however, moderated by occasional destructive high-velocity collisions. The relatively high viscosity of the dust and gas mixture throughout the disk must have been very important in producing a relatively uniform, rotational motion throughout the disk.

When "rocks" a few kilometres in size had been created new factors became important. Gravitational forces firstly increased the capacity of the larger "rocks" to accrete additional dust and smaller particles and, secondly, allowed some retention of material after even high-velocity collisions which would have destroyed smaller pieces.

The Giant Planets

The next stage is possibly the most difficult to model. Within a relatively uniform disk containing large numbers of rocks up to a few kilometres in diameter mixed within the residual dust and a large amount of gas, and extending to well outside Pluto's orbit, a small number of massive planets were formed. Some debris now remains as the comets and asteroids; however this debris and all the major planets, including the massive Jupiter, represent in total only a very small percentage of the original material of the solar nebula which was not condensed to form the sun.

It would appear that relatively quickly, during a period of 10^7 or 10^8 years, the large numbers of kilometre-sized objects, by collision and mutual gravitational attraction, formed the nuclei of the present planets and probably, in most cases, their major satellites also, in orbits relatively similar to their present ones. The planet-building process was most efficient at distances from the sun corresponding to the present orbits of Jupiter or Saturn, a compromise between temperature decreasing with distance from the sun, allowing a greater percentage of the total material to be solid and thus available for accretion, and density of material being greater closer to the sun. Most of the exo-planets so far discovered are gas giants.

The Jovian Planets

The outer or "Jovian" planets must have grown quickly, sweeping up hydrogen and helium gas as well as solid particles. Closer to the sun, the "icy" materials, still mainly in gaseous form, could not contribute very significantly to the

THE SOLAR SYSTEM

	Mean distance from Sun (millions of km)	Diameter km	Period of Revolution**	Average density (water = 1)	Number of Satellites
Sun	—	1,392,000	27·30 d		–
Mercury	57·9	4,878	87·97 d	5·4	0
Venus	108·2	12,104	224·70 d	5·2	0
Earth	149·6	12,756	365·26 d	5·5	1
Mars	227·9	6,795	686·98 d	3·9	2
Jupiter	778·3	142,985	11·86 y	1·3	67*
Saturn	1,427	120,537	29·46 y	0·7	60*
Uranus	2,869·6	51,119	84·01 y	1·3	27*
Neptune	4,496·6	50,538	164·79 y	1·8	14*
Pluto***	5,900	2,370	248·59 y	1·1	5

*These planets also have planetary rings. **d = days y = years. ***Scientists have reclassified Pluto (and the other bodies at the edge of the solar system in the Kuiper belt) (*see below*).

initial accretion process, so that only smaller planets could form. Owing to their smaller mass, gravitational field and thus lower "escape velocity," they were only able to accrete a small proportion of the heavier gas present within the inner part of the solar system. Thus, at present, these "terrestrial" planets are much denser than the outer "Jovian" planets, much smaller in size, and contain very little hydrogen or helium. The planet-building process was probably ended by two factors: the gravitational disruptive effect of the planets already formed and the enhanced "solar wind" of the young sun, which swept much residual dust and gas out of the solar system.

Before the process was complete, however, the gravitational energy released by the material falling onto the proto-planets plus the radioactive heating of short-lived isotopes present at the time of planetary formation were responsible for melting most of the bodies of the planets and probably all the larger satellites and asteroids.

A Continuing Process

This process allowed gravitational segregation of denser and lighter materials within the planets, and the production of the core, mantle and crustal regions of each of the terrestrial planets. Long after the dust and gas were driven from the solar system and the planet surfaces cooled and solidified, the residual larger rocks and asteroids, of which enormous numbers were originally still present, continued to be swept up by each of the planets. The record of this violent stage of the solar system's development can still be seen in the saturation cratering seen on the Moon, Mercury, and Mars.

Recent Explorations and Debates

In the past six decades, direct space exploration, using automated space probes (and manned spacecraft in the case of the Moon) has enormously increased our knowledge of the solar system. Notable have been the Viking, Pioneer and Voyager projects. The five space probes to Halley's comet in 1986 were also a huge success. Important discoveries have continued to be made by ground-based telescopes that are now comparable in some wavebands to the Hubble Space Telescope thanks to increasing sophisticated techniques such as the adaptive optics system that accounts for atmospheric ripples. More recently a large number of scientific missions have been launched including the X-ray multimirror telescope (XMM) to observe the universe, the Cluster II satellites observing the Earth's plasma environment, the Cassini mission to Saturn which also carried the Huygens probe to be dropped into Titan's atmosphere, the Mars Pathfinder mission, the Galileo trip to Jupiter, the Ulysses probe investigation of the Sun and the Rosetta mission to land on an asteroid in 2014. The Juno mission to Jupiter arrived in 2016. All have generated great quantities of exciting new scientific data. *See also* **T9(2)**.

New Solar System Discoveries

Until recently there were thought to be only nine planets in the solar system. But in 2003 a 10th planet was discovered. This planet, which was given the snappy name 2003UB313, is about three times as far from the Sun as Pluto and about as massive.

This discovery, along with the discovery of an orbiting object called Sedna some years later, opened a fierce debate: are they planets at all? What do we mean by a planet? Like 'life' the term 'planet 'has caused much debate.

The Reclassification of Planets

Many astronomers contested that 2003UB313 and Sedna were not planets, which led others to assert that Pluto was not a planet either. This controversy arose because of a large belt of icy objects beyond Neptune, known as the *Kuiper belt*. These objects are the result of incomplete planet formation in the outer Solar System. They are the remains of the original protoplanetary material.

Some astronomers suggested that Pluto itself was an object just like those in the Kuiper belt, and did not qualify as a planet. Others felt that the word 'planet' should be restricted to objects orbiting stars. Again, opinions as to the validity of this classification were offered and debated in newspapers. It became clear that the International Astronomical Union (the only body empowered to settle both matters) had no formal definition of

SOME ASTRONOMICAL DISTANCES

(1 light-year = $9·46 \times 10^{12}$ km).

Object	Distance from Earth (light-years)	Velocity of recession (km per second)	Object	Distance from Earth (light-years)	Velocity of recession (km per second)
Sun	$1·6 \times 10^{-5}$	- -	Andromeda Galaxy	$2·2 \times 10^{6}$	−299
Nearest star (Proxima Centauri) . .	4·2	—	Galaxy in Virgo	$7·5 \times 10^{7}$	1,200
Brightest star (Sirius) .	8·6	—	Galaxy in Gt. Bear	10^{9}	14,900
Pleiades	410		Galaxy in Corona Borealis	$1·3 \times 10^{9}$	21,600
Centre of Milky Way .	$3·0 \times 10^{4}$	—	Galaxy in Bootes	$4·5 \times 10^{9}$	39,300
Magellanic clouds (the nearest galaxies) .	$1·6 \times 10^{5}$	—	Very remote quasi stellar object	$\sim 1·2 \times 10^{10}$	~280,000

"planet", and an authoritative decision on classification was needed.

Problems of Definition

So why is 'planet' hard to define? Part of the problem is that there are three areas in which the definition could be constructed: first, the *physical properties* of the body itself; second, its *orbital properties* and finally its *formation mechanisms* and *histories*. It is argued that any definition of a planet will be some mix of these characteristics. However, the principal reason for the controversy is that there is no good scientific way to keep Pluto a planet without doing serious disservice to the remainder of the solar system.

Dwarf Planets / Plutoids / Planet Nine

The problem was resolved in August 2006 when a new class of dwarf planets was officially designated. Pluto was removed from the list of *classical planets* (as the other 8 planets were now called) and was joined with Charon, Ceres, Eris (2003 UB313) and the tiny 2012 VP113 to form a new group of *dwarf planets*. The status of Pluto was soon changed yet again, however, in 2008 to become a *plutoid* (*see below*). Eris (the largest dwarf planet) even has its own moon, Dysnomia.

A new category (*plutoid*) was proposed for those dwarf planets beyond Neptune which take more than 200 years to orbit the Sun. Eris (formerly known as Xena), Charon, Haumea, Makemake, Sedna and 2012 VP113 are in this plutoid group.

To add to the problem, early in 2016 it was announced that a new, full-sized planet (10 times the size of Earth) could exist way out nearer the edge of the solar system. It was provisionally named Planet Nine, taking 20,000 years to orbit the Sun.

Extrasolar Planets

Over the last 25 years, scientists have discovered planets orbiting other stars, called *extrasolar planets*. The planets themselves have not been seen – we can only see stars at such large distances because they emit light so powerfully – but they were detected because astronomers observed some stars 'wobbling', from which it was deduced that invisible objects nearby were exerting a gravitational pull.

Not surprisingly, the first such planets to be discovered were very large, Jupiter-sized gas giants.

That in itself is not surprising as the technique being used to observe these planets is biased towards finding objects that are big enough and close enough to exert a noticeable gravitational effect on the visible star. Indeed, if alien astronomers performed the same experiments on our own Sun, they might discover Jupiter and possibly Saturn, but they would not be able to detect any other planets.

However, the fact that these planets are so close to the stars they are orbiting is strange. The classical theory of planet formation suggests that big planets like Jupiter and Saturn are formed at much greater distances from the primary star, since the heat of the star during the formation of the stellar system would have otherwise prevented materials from accumulating to form such a big planet. New theories have been devised to explain these strange planets and their odd locations. None are yet satisfactory. In recent years, with improved telescopes and more advanced detection techniques, the number of exoplanets (both large and small) has risen rapidly (and thousands more await confirmation). Billions more almost certainly exist. The Kepler Mission alone detected hundreds of such planets. Entire planetary systems have now been found. These exoplanets also provide proof that planets *do* migrate. One exoplanet has been found with a massive ring system, over 200 times larger than the famous ring systems of Saturn. Planets far older than Earth have been discovered.

An Earth-like planet was found in 2016 which orbits Proxima Centauri, our nearest stellar neighbour, only 4 light years away.

Significant Planetary Missions

(i) Mercury

A space mission to Mercury is quite a challenge. Being closest to the Sun, it is difficult to reach which is why Mercury has only been visited by one spacecraft, Mariner 10 in 1974 and 1975. Much about Mercury remains mysterious. Two new spacecraft will visit Mercury in the next decade. The first called *Messenger* was launched by NASA in 2004 and began to orbit Mercury in 2011 after several flybys. The second spacecraft called BepiColombo set off in 2013 on a journey due to last over four years. These missions will bring us new images and data about this least explored planet.

(ii) Venus

Until fairly recently Venus had been a low priority for planetary probe programs, but ESA committed itself to a Venus orbiter mission named 'Venus Express' which was a follow on from the Mars Express mission. Many of the instruments on the mission were simply upgraded versions of those on the Mars Express platform. After a 153 day cruise the spacecraft arrived at Venus in 2006 and it went on to map the surface and atmosphere of the planet.

(iii) Mars

Mars has been known for thousands of years. It has been extensively studied from ground-based observatories. However, little can be understood from the Earth even with very large telescopes. In 2004 the Mars Expedition Rovers 'Spirit' and 'Opportunity' successfully landed on Mars, their mission to send back geological data. They were still operating after more than four years on Mars, and they have sent back many astonishing pictures.

There are also the Mars orbiters (Mars Global Surveyor, Mars Odyssey, and Mars Express) currently traveling around Mars, carefully mapping the surface and composition and Martian environment.

The exploration of Mars continues. In late 2005 NASA's Mars Reconnaissance Orbiter set sail for Mars. It arrived in 2006 to begin collecting data. The plan was to find safe and scientifically worthy landing sites for future exploration, so it was fitted with cameras to zoom in for extreme close-up photography of the Martian surface and a sounder to find subsurface water.

(iv) Saturn

The only mission dedicated to exploring Saturn was the NASA Cassini space probe, which entered Saturn's orbit in June 2004. Cassini carried the Huygens probe, the first planetary lander built by ESA. Cassini was the biggest and most expensive interplanetary probe ever built and is the first to explore the Saturn system of rings and moons from orbit. Cassini immediately began sending back intriguing images and data. In January 2005 the Huygens Probe fell into the thick atmosphere around Titan, one of Saturn's moons. Titan contains nitrogen, methane and other organic (carbon-based) molecules. Indeed, conditions on Titan are believed to resemble those on Earth 4·6 billion years ago.

(v) Pluto

In July 2015 the New Horizons spacecraft having travelled 4·5 billion kilometres and having been launched back in 2006 passed by Pluto, sending back a welter of tantalising data. It appeared to show a white heart of nitrogen ice (now named the Tombaugh Region), evidence that Pluto is still geographically active, and also an absence of impact craters. On Pluto, frozen flakes of nitrogen fall as snow. Both Pluto and its moon Charon revealed high mountains (some two miles high), deep canyons, ragged cliffs and a youthful crust.

II. PHYSICS—THE FUNDAMENTAL SCIENCE OF MATTER

WHAT PHYSICS IS ABOUT

Introduction

Anyone compelled by curiosity or professional interest to look into contemporary journals of pure physics research is soon struck by the fact that the traditional division of physics into "heat, light, sound, electricity, and magnetism" has become very blurred.

Current Divisions of Physics

Two different, though complementary, sections can be distinguished. First, there is the physics concerned with the properties of matter in bulk, with solids, liquids, and gases, and with those odd but very important substances, such as paints, plastic solutions, and jelly-like material, which are neither properly solid nor liquid. In this vast domain of physics questions like this are asked: Why is iron magnetic, copper not? What happens when solids melt? Why do some liquids flow more easily than others? Why do some things conduct electricity well, others badly, some not at all? During the last century, particularly the last few decades, it has become clear that such questions can be answered only by raising and solving others first. In particular, we must ask: (i) Of what nature are the invisible particles of which matter is composed? and (ii) How are those particles arranged in bulk matter?

The first of these two questions has generated the second major category of modern physics: this is the physics of particles and of the forces that particles exert on each other. In this field which represents science at its most fundamental questions like this are asked: If matter is composed of small units or particles, what are they like? How many kinds of particle are there? Do the particles possess mass? electric charge? magnetism? How do the particles influence each other? How can their motion be described and predicted?

The discussion which follows has been divided into two main parts (1) **Particles and Forces**, and (2) **The Properties of Matter in Bulk**, with part (1) describing the microscopic structure of matter and part (2) its macroscopic properties.

PARTICLES AND FORCES

Aristotle to Newton

The inference that matter should be composed of small particles or atoms originated, it is true, in classical times. The atomic idea was an attempt to solve the age-old problem of matter and its peculiar properties. The ancients had provided themselves with two solutions to the problem of matter:

(i) **The theory of the four elements** (earth, water, fire, air), from which all different forms of matter were composed by selecting different ratios of the four ingredients. This approach had been used by traditional philosophy and was adopted by Aristotle.

(ii) **The theory of atomism** which postulated the existence of atoms and empty space.

Atomism remained very much in the background in the development of Western Science and persisted even longer in the Arab world. The idea that matter is composed of "small units" was in reality forced into the mental development of mankind by the repeated application of the process of dimension halving. By the time of Newton atomism had come to the fore and Newton considered that God had made the Universe from "small indivisible grains" of matter. Nevertheless, the search for the "philosopher's stone" was still, in the seventeenth century, the main pursuit of many scientists, but the new chemistry of the seventeenth century made use of atomistic concepts. Newton's physics was a mechanics concerning particles in a vacuum and when Boyle described his gas law (*i.e.*, Pressure × Volume is constant at a fixed temperature) he visualised matter as composed of particles with specific qualitative properties. It was, of course, the advance of experimental techniques which enabled scientists to test theories on the nature of matter.

Dalton and Atomic Theory

The modern view of atomism need be traced no farther than the beginning of the nineteenth century when Dalton and his contemporaries were studying the laws of chemical combination using precise weighing techniques. By that time the distinctions between elements, compounds, and mixtures were already made. Compounds and mixtures are substances which can be separated into smaller amounts of chemically distinguishable constituents.

Elements (*see* **T56**) cannot be so divided. In a mixture the components may be mixed in any proportion and sorted out again by non-chemical means. In a compound the elements are combined in fixed proportions by weight. This last fact gives the clue to atomic theory.

Dalton pointed out that the fixed combining weights of elements could easily be explained if the elements consisted of atoms which combined in simple numerical ratios, *e.g.*, 1 atom of element A with one of B, or one of B with two of C, and so on. For instance, 35·5 g of chlorine combine with 23·0 g of sodium to make 58·5 g of ordinary salt. If we assume one atom of chlorine links with one of sodium, then the atoms themselves must have weights in the ratio 35·5 to 23·0.

This turns out to be consistent with the combining weights of chlorine and sodium in all other compounds in which they both take part. Sometimes two elements combine in several different proportions by weight. But this is easily explained by assuming that the atoms link up in a variety of ways *e.g.*, one iron atom with one oxygen, or two irons with three oxygens, or three irons with four oxygens. Then the three different combining proportions arise from the three different numbers of atoms, *using in each case the same ratio of oxygen atom weight to iron atom weight.*

Atomic Weight

Over the century and a half since Dalton, these ideas have been repeatedly tested by chemical experiments. Nobody now doubts that every chemical element has atoms of characteristic weight. The atomic weight or more properly the relative atomic mass, of an element is by international agreement expressed relative to one isotope (*see* below) of carbon, namely carbon-12 which is given the relative mass of twelve. These numbers are only ratios; the real weight of one single oxygen atom is $2{\cdot}7 \times 10^{-23}$ g.

Valency

That the combinations of atoms in definite proportions was necessary to produce compounds, or more correctly molecules, was known from 1808. The reason why only one atom of sodium and one of chlorine was required to produce one molecule of salt was unknown. Further the seemingly odd combinations of two atoms of hydrogen (H) with one of oxygen (O) to give water (H_2O), while only one atom of hydrogen could combine with chlorine to give hydrogen chloride (HCl) could not be explained. This situation was not resolved until around 1860, when the chemical formulae of many molecules were known. It was then discovered that homologies existed in the elements, for example the series Na, K, Rb, Cs, or Fl, Cl, Br, I, and this culminated in the Periodic Table of the elements (*see* **T56**).

Determining Valency

The valency of an atom was determined by its position in the periodic table and determined by the number of electrons which the atom has orbiting its nucleus. Atoms combined to form molecules in a manner which maintained the number of "valence" electrons in a stable grouping of 2, 8, or 18 (*see later*). For example, sodium has one valence electron and chlorine seven, therefore the combination NaCl gives the stable grouping of eight; hydrogen has one and oxygen six, hence it requires two atoms of hydrogen and one of oxygen to give one stable molecule, H_2O. Other more complicated molecular structures and types of bonding between atoms are dealt with in the chemistry section. This discovery of particles smaller than the atom itself was necessary to fully comprehend the nature of valency in atomic combinations.

J. J. Thomson and the Electron

Matter is electrically uncharged in its normal state, but there exist many well-known ways of producing electric charges and currents—rubbing amber, or rotating dynamos, for example. It is therefore necessary to have some theory of electricity linked to the theory of matter. The fundamental experiment in this field was made by J. J. Thomson when, in 1897, he discovered the electron.

If you take two metal electrodes sealed inside a glass vessel and if the pressure of the air is reduced from atmospheric pressure, 76 cm of mercury, to 1 mm of mercury by mechanical pumping and then a high voltage, several kilo-volts, is applied to the electrodes, the negative electrode emits a "radiation" which causes the walls of the tube to glow. The rays are called *cathode rays*. The discovery of the electron was essentially a clarification of the nature of cathode rays. Thomson showed that they were streams of particles with mass and negative electric charge and a general behaviour unlike any other atomic particle known at that time. The importance of this discovery for the world of science cannot be overestimated, and its technical progeny are in every home and factory in X-ray machines, television tubes, and all electronic devices.

Rutherford–Bohr Atom

Since the electrons emerge from matter, they are presumably parts of atoms. The relation between the negative electrons and the positively charged constituents of matter was elucidated by the great experimenter Rutherford and the great theoretician Bohr. Their work, just before the First World War, showed that the positive charge, together with almost all the mass, is concentrated in the central core or nucleus of the atom about which the very light-weight electrons revolve. The diameter of an atom is about 10^{-8} cm, roughly one three-hundred-millionth part of an inch. The central nucleus has a diameter about 10,000 times smaller still. The nucleus and the electrons hold together because of the electric attraction between them.

The positive charge of the nucleus is responsible for holding the electron in the region of space around the nucleus. The electrostatic Coulomb force, if left on its own would quickly attract the electrons into the nucleus but since the electrons move in orbits, circular and elliptical, they experience an outward centrifugal force which balances the inward electrostatic force. The mechanism is similar to that which holds the earth in orbit around the sun, only here a gravitational force replaces the effect of the Coulomb force. Modern theories of the electronic structure of atoms are quantum mechanical (*see below*).

At this stage work could, and did, go on separately along several different lines:

(i) Electrons could be studied on their own. Nowadays the handling of beams of electrons of all sizes and intensities has become a major branch of technology.

(ii) The nucleus could be treated as a special problem, and this led to the mid-20th century flowering of nuclear physics, to the atomic bomb, and to nuclear power.

(iii) The behaviour of electrons in the atom could be analysed; this is the great domain of atomic physics which spreads into many other sciences as well.

Volumes have been written about these three fields, such is their crucial importance.

The Electron

Electrons are expelled from solids by light, heat, electric fields, and other influences. It has therefore been possible to study beams of electrons on their own *in vacuo*. Electrons inside matter, either as constituents, or temporarily in transit, can also be observed by their innumerable effects. These observations all show the particles to be indistinguishable one from another; all electrons are the same wherever they come from. They have a definite mass ($9{\cdot}11 \times 10^{-28}$ g), a negative electric charge, a magnetic moment, and a "spin" (intrinsic rotatory motion). Only recently have scientists been able to sub-divide electrons into three component parts.

The electronic charge has long been used as a basic unit of charge in atomic physics. The electron has come to be the best known of all the "fundamental particles." It is now used in research as probe for studying the structure of matter, for which it is ideally suited, since it is very much smaller than an atom. A whole field of electron-scattering research which studies the nature and structure of solids, liquids, and gases is being actively conducted in many laboratories.

The Nucleus

The early research programmes in nuclear physics were greatly facilitated by the occurrence in nature of certain unstable (radioactive) nuclei which emit fast-moving fragments. The latter can be used as projectiles to aim at other nuclei as targets; the resulting impacts yield much valuable information. This technique still dominates nuclear physics, though nowadays the projectiles are artificially accelerated by one or other of the large costly machines designed for the purpose.

Protons and Neutrons

The most important early discovery was that the nucleus consists of two types of fundamental particle—the positively charged *proton* and the electrically neutral *neutron*. These two are of nearly equal mass (about 1,800 times that of the electron), and like electrons, have a magnetic moment and spin. The proton charge is equal to the electron charge, though opposite in sign. Consider a moderately complex nucleus like that of iron. This usually has 30 neutrons and 26 protons. Its atomic weight therefore depends on the total number of neutrons plus protons, but the total charge depends only on the number of protons—called the *atomic number*. The latter is denoted by Z while the total number of neutrons plus protons is called the *mass number* and denoted by M. A species of nucleus with given values of Z and M is called a *nuclide*. Z is also the number of electrons in the atom, since the atom as a whole is electrically neutral. The atomic number determines the chemical nature of the atom (*see below*), so that by altering the number of *neutrons* in a nucleus we do not change the chemical species.

It is thus possible to find—and nowadays to make—nuclei of the same element which nevertheless differ slightly in weight because they have different numbers of neutrons. These are called *isotopes*. Iron isotopes are known with anything from 25 to 36 neutrons, but all have 26 protons. Thus a set of isotopes consists of the various nuclides that have the same Z but different M's.

When the atomic properties of isotopes are measured it is found that small, hyperfine differences in the motions of the electrons around the respective nuclei exist. These result from the different total spin of the isotopes and its effect on the orbiting electrons. This influence of atomic properties by nuclear effects is important in that it provides a link between different fields of research.

Stable Nuclides

The protons and neutrons in a nucleus are bound together by strong forces called *nuclear forces.* In many cases, the forces are so strong that no particles ever escape and the nucleus preserves its identity. There are two hundred and seventy-four different combinations of neutrons and protons of this kind, and they are called the *stable nuclides.* The earth is largely composed of such stable nuclides, because any unstable ones have, in the course of time, spontaneously broken up into stable residues.

Nevertheless, there are some unstable nuclei left on earth. They give rise to the phenomenon of radioactivity which was discovered by Becquerel in 1893.

Unstable Nuclides: Radioactivity

Becquerel found that certain chemicals containing uranium gave off rays capable of blackening a photographic plate, and shortly afterwards Marie and Pierre Curie discovered more substances, including radium, which produce similar but stronger effects. By now, about fifty chemical elements having radioactive properties are known to exist on earth, some, like radium, being strongly radioactive, others, like potassium, being so weak that the radiations are difficult to detect. These are called the *natural radioactive nuclides.*

The main facts about radioactivity are as follows: it is a *nuclear* phenomenon and (with minor exceptions) proceeds quite independently of whatever the electrons in the atom may be doing. Thus, the radioactivity of an atom is not affected by the chemical combination of the atom with other atoms, nor by ordinary physical influences like temperature and pressure. The radioactivity consists of the emission by the substance of certain kinds of rays. The early workers, Rutherford being the giant among them, distinguished three kinds of rays labelled α, β, and γ. These are described below. Whatever kind of ray is examined, it is found that the radiation from a given sample decreases gradually with time according to a definite law which states that the intensity of radiation decreases by half every T seconds. The number T, called the half-life, is constant for each radioactive material, but varies enormously from substance to substance. For instance, radium decreases its activity by a half every 1,602 years, whereas the half-life of one of the astatine isotopes is about $0{\cdot}1 \times 10^{-6}$ sec.

Radioactive Emissions

The three most well-known types of radioactive emission are quite distinct from one another.

(i) **α-rays** or α-particles consist of two protons and two neutrons bound together. They are ejected from the radioactive nucleus with one of several well-defined speeds. These speeds are high, often of the order 10^9 cm per sec. Two protons and two neutrons are the constituents of the nucleus of helium, and α-particles are thus fast-moving helium nuclei.

(ii) **β-rays** are moving electrons. They may emerge from their parent nucleus with any speed from zero to a definite maximum. The maximum speed often approaches that of light, and is different for each isotope. The electron has a positively charged counterpart, the positron (see below), and β-rays are sometimes positrons. To distinguish the two cases, the symbols β^- and β^+ are used. The naturally occurring β-radiations are almost all β^-.

(iii) **γ-rays** travel with the speed of light because they are in fact electromagnetic waves differing from light only in the extreme shortness of their wavelength. They have no electric charge.

It is unusual, though not unheard of, for the same radioactive substance to emit both α- and β-rays. On the other hand, γ-rays frequently accompany either α- or β-rays.

γ-rays pass through matter easily; in fact, they are extra penetrating X-rays. α-rays can be stopped by thin sheets of tissue paper. α-rays brought to rest pick up a pair of electrons from the surrounding matter and become neutral helium atoms, and helium gas from this source is consequently found imprisoned in certain radioactive rocks. β-rays are intermediate in penetrating power between α- and γ-rays.

We must now try to interpret these observations.

Radioactive Disintegration

A nucleus is a collection of neutrons and protons interacting with each other and possessing collectively a certain amount of energy. Just as some human organisations lose their coherence if they accept too many members, so nuclei can remain stable only if (i) the total number of particles is not too great, and (ii) neutrons and protons are there in suitable proportions. Radioactive nuclei are the ones for which either or both these conditions do not hold. Sooner or later such nuclei eject a fragment, thus getting rid of some energy they cannot contain. This is called a *radioactive disintegration*, and the fragments are the α-, β-, and γ-rays. α-emission relieves a nucleus of two neutrons and two protons and some energy; γ-emission simply carries off excess energy without altering the number or kind of particles left behind. β-emission is more complicated. There are no electrons normally present in a nucleus, but they are suddenly created and explosively emitted if a neutron changes into a proton; positive electrons are similarly generated if a proton changes into a neutron. β-emission is therefore a mechanism for changing the ratio of protons to neutrons without altering the total number of particles.

Both α- and β-emission change the Z of a nucleus, and the product, or daughter nucleus, is a different chemical element. α-emission also changes the M. It might happen that the daughter nucleus is unstable, in which case it too will disintegrate. Successive generations are produced until a stable one is reached. Part of such a family tree is shown below. The symbols above the arrows show the kind of rays emitted at each stage, the figures are the mass numbers, M, and the names and symbols of chemical elements can be found on **T56–7**.

$$\mathrm{U}^{238} \overset{\alpha}{\rightarrow} \mathrm{Th}^{234} \overset{\beta}{\rightarrow} \mathrm{Pa}^{234} \overset{\beta}{\rightarrow} \mathrm{U}^{234} \overset{\alpha}{\rightarrow} \mathrm{Th}^{230} \overset{\alpha}{\rightarrow}$$

$$\mathrm{Ra}^{226} \overset{\alpha}{\rightarrow} \mathrm{Rn}^{222} \overset{\alpha}{\rightarrow} \mathrm{Po}^{218} \overset{\alpha}{\rightarrow} \mathrm{Pb}^{214} \overset{\beta}{\rightarrow} \mathrm{Bi}^{214} \overset{\beta}{\rightarrow}$$

$$\mathrm{Po}^{214} \overset{\alpha}{\rightarrow} \mathrm{Pb}^{210} \overset{\beta}{\rightarrow} \mathrm{Bi}^{210} \overset{\beta}{\rightarrow} \mathrm{Po}^{210} \overset{\alpha}{\rightarrow} \mathrm{Pb}^{206}$$

(Pb^{206} is stable lead).

This family exists naturally on earth, because the head of the family, U^{238}, has so long a half-life ($4{\cdot}5 \times 10^9$ years) that there has not yet been time enough since its formation for it to have disappeared.

Artificial Radioactivity

Many new radioactive isotopes have long been man-made. All that is required is to alter the M or Z (or both) of a stable isotope to a value which is incompatible with stability. The means for doing this is *bombardment, i.e.*, stable nuclei are exposed to the impacts of atomic particles such as streams of protons from an accelerator, the neutrons in an atomic reactor, or simply the α-particles from another radioactive substance.

The new material is called an *artificially radioactive isotope.* Artificial radioactivity is not different in kind from that of the naturally radioactive substances, but the half-lives are usually on the short side. Indeed, the isotopes in question would exist in nature but for the fact that their short half-lives ensured their disappearance from the earth long ago.

Suppose a piece of copper is exposed to the intense neutron radiation in an atomic reactor. The more abundant of the two stable isotopes of ordinary copper has thirty-four neutrons and twenty-nine protons (*i.e.*, $Z = 29$, $M = 63$). In the reactor many (not all) of these nuclei absorb a neutron, giving an unstable copper nucleus with $Z = 29$, $M = 64$. When removed from the reactor the specimen is observed to be radioactive with a half-life of 12·8 hours. It is somewhat unusual in that it gives out both β^- and β^+ rays.

Some nuclei emit electrons, leaving a daughter nucleus with one more positive charge than copper, *i.e.*, a zinc nucleus ($Z = 30$, $M = 64$). One neutron has become a proton, and the resulting zinc nucleus is stable. The others emit positrons, leaving behind a nucleus in which a proton has been turned into a neutron ($Z = 28$, $M = 64$); this is a stable nickel nucleus.

The overall process is one example of the artificial transmutation of the chemical elements which is now a commonplace of nuclear physics. It was first discovered by Irene and Frederick Joliot-Curie in 1934.

Lack of a Complete Theory

Consider now a collection of, say, one million radioactive nuclei of the same kind. It is impossible to tell exactly when any one of them will disintegrate; it is a matter of chance which ones break up first. All we know is that, after a time equal to the half-life, only a half a million will survive unchanged. In general, the more excess energy a nucleus has, the more likely it is to break up, and therefore the shorter the half-life of that particular nuclear species. In principle, to calculate the half-life theoretically, one would have to have a reliable theory of nuclear forces and energies. This is still being sought after, so it is probably fair to say that while the laws of behaviour of radioactive isotopes are well and accurately known, the *explanation* of this behaviour in terms of the properties of protons and neutrons is by no means complete.

Nuclear Fission—Chain Reaction

A discovery important not just for nuclear physics but for the whole of mankind was made by Hahn and Strassman in 1939. This was the discovery of nuclear fission in uranium. One of the natural isotopes of uranium is an unstable one, U^{235}, with 143 neutrons and 92 protons. It normally shows its instability by emitting α- and γ-rays. If uranium is bombarded with neutrons, some U^{235} nuclei temporarily gain an extra neutron, which makes them even less stable. This they show by splitting into two roughly equal parts, called fission fragments, together with two or three neutrons.

There are two highly important things about this disintegration. One is that the two or three neutrons can promote further disintegrations in other uranium nuclei, and the process can therefore be self-propagating: it is then called a *chain reaction.* The other is that the total mass of the fission products is less than that of the original nucleus. This mass difference does not disappear without trace; it turns into energy according to a formula discussed later.

Nuclear Fusion

The ability of two light nuclei to combine and form a heavier nucleus is called fusion. A reaction of this nature does not form a chain process but proceeds in singly induced reactions. A typical fusion reaction is the formation of a helium nucleus (mass 3) from two deuterium nuclei which are made to collide at an energy of 60 keV (speed of $2{\cdot}4 \times 10^6$ m/s)

i.e., $^2D_1 + {}^2D_1 \rightarrow {}^3He_2$ (0·82 meV) + n(2·45 meV)

where the $^3He_2$ particle has kinetic energy of 0·82 meV and the free neutron has free kinetic energy of 2·45 meV. This type of reaction is exoenergetic, the additional kinetic energy coming from the tighter binding of the nucleus in ^3He than in the two separate deuterium nuclei. The energy released in this form of nuclear reaction is much more than that in a fission process and is responsible for the emitted energy of the sun which burns hydrogen to form helium.

Applications of Nuclear Reactions

The world has two uses for the energy released in nuclear reactions:

(1) nuclear weapons;
(2) nuclear power plants.

The only nuclear bombs to be used in anger employed the fission chain reaction proceeding at a rapid rate which quickly becomes uncontrollable and produces a tremendous explosion. The second generation of nuclear warhead uses the fusion reaction, which is initiated by a fission-reacting detonator to produce an even more destructive blast. The third generation of nuclear warhead uses the large flux of very energetic neutrons to kill biological material, but the blast effect is essentially zero, hence attacks with neutron bombs leave most non-biological material and structures intact.

In the second application the nuclear fission process is controlled to provide a constant source of energy to drive turbines which produce electricity.

Both uses represent epoch-making technical achievements, but mankind has yet to show itself capable of bearing sanely the burden of responsibility which nuclear physicists have laid upon it. One thing is certain: the discoveries will not cease. Already, other fissionable elements have been made and used; new chemical elements have been created; nuclear plants ("atomic piles") have stimulated great demands for new materials that will stand the heat and radiation inside the reactor, and this promotes research in other fields of science; irradiation inside an atomic pile gives new, and potentially useful properties to old materials; nuclear power drives ships and submarines. It is difficult to write even briefly about contemporary nuclear physics without feeling keenly the ambiguity of its powerful promises.

Atoms

A nucleus surrounded by its full complement of electrons is an electrically neutral system called an atom. Neither the atom as a whole, nor its nucleus, counts as a "fundamental particle" because either can be subdivided into more elementary parts, thus:

$$\text{atom} \rightarrow \text{electrons} + \text{nucleus} \rightarrow \text{electrons} + \text{neutrons} + \text{protons}$$

The chemical identity of the atoms of a given element, which was Dalton's key idea, depends entirely on the number and motion of the electrons. For example, the simplest element, hydrogen, has one proton for a nucleus, and one electron. The latter is comparatively easily detached or disturbed by the electric forces exerted by neighbouring atoms, consequently hydrogen is reactive chemically, *i.e.*, it readily lends its electron to build chemical structures with other equally co-operative elements. The second element, helium, has a nucleus of two protons and two neutrons; outside are two electrons in a particularly stable arrangement.

Both electrons orbit the nucleus in the same spacial orbit, but with their spin directions opposite and at 90° to the plane through the nucleus and the electrons. This pair of electrons is so difficult to disarrange that the special name of closed shells has been coined to cover such cases.

The fact that two electrons can be present in the same orbit is only possible if their spins are antiparallel (Pauli Exclusion Principle). In the case of a stable group of eight electrons they arrange themselves in groups of two and their spins antiparallel. Helium with its closed shell will not react chemically, whereas hydrogen, which has an open shell of only one electron, will react very quickly with other atoms.

As the nuclear charge increases, different electron arrangements of greater or lesser stability succeed one another, with every so often a closed shell corresponding to one of the chemically inert gases neon, argon, xenon, krypton.

Such considerations, pursued in sufficient detail, enable atomic physics to account for all the differences and similarities among the chemical elements and, in principle at least, for all other facts of chemistry as well.

Ions

Changes in the atomic properties of an atom are accomplished by altering the position of any electron from one orbit to another. In the limit when an electron is completely removed from the atom, leaving it positively charged, the atom is said to be ionised and is called a positive ion. An atom can be singly or multiply ionised up to a level equal to the number of electrons existing in the neutral atom. In addition, atoms can, through distortion of the existing electrons, accept an additional electron and become negative ions. These can be formed in a resonance scattering process and exist only for life-times of only 10^{-14}s or be formed by chemical reactions. The roles played by negative and positive ions in the upper atmosphere of the earth and stellar atmospheres have been of special interest to atomic physicists since the 1930s.

Maxwell and Electromagnetic Waves

Atoms are held together by the electric attraction of the nucleus for the electrons. Finer details of atomic behaviour depend on the magnetic moments of the particles. Any moving charged particle gives rise to magnetic effects, and in the dynamo a coil moving in a magnet produces an electric current. It can be seen therefore that electric and magnetic phenomena are intimately linked. Any region of space subject to electric and magnetic influences is called an *electromagnetic field.*

In 1862, before the discovery of the electron, Maxwell, while still in his twenties, had perfected a general theory of the electro-magnetic field. This theory today still describes correctly almost all electro-magnetic phenomena. The elegance of this theory is difficult to appreciate, but it alone was the only theory of pre-twentieth century physics which satisfied the prerequisites of Einstein's relativity theory (1905), *i.e.*, inherent in its structure was the concept of relativistic invariance. *Inter alia*, he proved that disturbances in the electric and magnetic conditions at one place could be propagated to another place through empty space, with a definite velocity, just as sound waves are propagated through air. Such electromagnetic disturbances in transit are called *electromagnetic waves*, and their velocity turned out experimentally to be the same as that of light and radio waves—which was a decisive argument to show that both of these phenomena are themselves electro-magnetic waves.

Einstein and Photons

In the years between about 1900 and 1920 this view was upset by Planck, Einstein, Millikan, and others, who focused attention on phenomena (radiant heat, photoelectricity) in which light behaves like a stream of particles and not at all like waves. A wave and a particle are two quite different things, as anyone will admit after a moment's contemplation of, say, the ripples on a pond and a floating tennis ball. The acute question was: is light like waves or particles?

Theoretical physicists have devised means of having it both ways. To say that light behaves as particles means that the waves of the electromagnetic field cannot have their energy subdivided indefinitely. For waves of a given frequency, there is a certain irreducible quantity of energy that must be involved whenever light interacts with anything. This quantity is the product hv where v is the frequency and h is a constant named after Planck. Each such unit is called a *quantum of the electromagnetic field* or a *photon* and is counted as one of the fundamental particles. Frequencies and wavelengths vary widely. Typical wavelengths are: radio—hundreds or thousands of metres; radar—a few centimetres; visible light—5×10^{-5} cm; X-rays—10^{-8} cm.

De Broglie and Particles

Since it seemed possible to attribute particle properties to electro-magnetic waves, then why not associate wave properties with particles. If an electron (mass m) is travelling with a velocity of v cm/s, then De Broglie (1923) suggested that its characteristic wavelength would be given by the relation $mv\ \lambda = h$; for example if $v = 10^3$ m/s, $m = 9 \times 10^{-31}$ kg, $h = 6{\cdot}626^{-34}$ joules-seconds, then $\lambda = 7{\cdot}36 \times 10^{-7}$ m, which is the same wavelength as red light. This proposal was confirmed in 1927 by Davisson and Germer when they showed that electrons could produce diffraction, a property until then only associated with light. These wave-like properties are now known to exist for all particles, and we now consider a particle with momentum mv to behave like a wave of wavelength $\lambda = h/mv$.

De Broglie made his revolutionary assertion in his doctoral thesis, and his examiners were so uneasy about the validity of the hypothesis that they were prepared to fail the young man in his examination. Happily for De Broglie, Einstein was visiting that particular university and he was asked his opinion of the idea; his reply ensured success for De Broglie and saved the examiners from future embarrassment.

Molecules

Electrical attractions and interactions of various kinds can cause atoms to combine with each other or themselves to form molecules. Two similar atoms, say hydrogen, combining to form the homonuclear diatomic molecule H_2, while two different atoms, hydrogen and chlorine, will form a heteronuclear diatomic molecule HCl. Molecules have a wide range of complexity, from simple pairs of atoms to highly intricate spirals and chains composed of thousands of atoms. The biological basis of all life is, of course, molecular in both origin and function.

Excited Atoms

Like nuclei, atoms, when given excess energy (insufficient to ionise them), will absorb the energy in one of the electrons, which is then displaced from its equilibrium state to a state (or orbit) of higher energy. It will remain there for typically 10^{-8} seconds before returning to its equilibrium position with the excess energy being emitted as light. The time an atom remains in its excited state can exceed 10^{-8} seconds; lifetimes of 0·1 second are known, and these metastable states are prevented by the atomic properties of the atom from decaying quickly to their equilibrium states. The colour of the light emitted is characteristic of the atom involved, with the more energetic transitions giving blue light while the less energetic transitions give red light. Hence the emitted colour (or wavelength) of the light can be used for chemical identification and study of the various transition probabilities in atoms.

Herein lies the explanation of innumerable natural and technical phenomena, such as the colours of glowing gases whether they exist in the sun and stars, in aurora, or in street-lamps and neon signs. Herein also lies the reason for the importance of spectroscopy, which is the study of the characteristic radiation from excited states for spectroscopy is not only a useful tool for the chemical identification of substances ("spectroscopic analysis") but was one of the main routes along which twentieth-century physicists broke through to a knowledge of the inner nature of the atom.

Forces in Nature

Nature uses four, at high energies three, different forces to make one particle interact with another. The weakest force is **gravity** which although present at all particle interactions, is insignificant in atomic and nuclear interactions. Gravity controls the mass distribution in the universe and the force has an infinite range of interaction.

The **electric force** which also has an infinite range of interaction is much stronger than the gravitational force and is responsible for the binding forces inside atoms by the attraction of nuclei for electrons.

Inside the nucleus two types of interaction take place which require different forces for their existence:

(1) the forces which hold neutrons and protons together in the nucleus and this is the **strong force,** and

(2) the **weak force** which controls the changes in charge state of nucleons, *e.g.*, the β-decay process when a neutron in a nucleus changes into a proton with the ejection of an electron is controlled by the weak force.

Both these nuclear forces are short-range with their radius of influence approximately 10^{-13} cm, with the weak force acting on all matter and the strong force acting on quarks only. In today's parlance, gravity will act on any particle with mass, the electric force on any particle with charge, the strong nuclear on quarks and the weak nuclear on quarks and leptons (*see below*).

Quarks appear to experience short-range freedom of movement combined with a long-range binding. The proton, *i.e.*, the nucleus of atomic hydrogen, is composed of three quarks which move about freely within the shell of the proton; only when one quark tries to escape across the boundary of the proton does it experience a force which rebinds into the proton. Before we discuss further the interactions of these forces we must describe the range of particles which exist in physics.

Elementary Particles

When considering the word elementary in this context the reader should be wary of thinking that it implies some degree of absoluteness. The elementary mass of any particlular particle is always highly qualified and subject to change. When a particle is discovered physicists measure its properties, *i.e.*, mass, electric charge, and spin, and determine which of the four forces to which it is subject. In addition, its life-time must be determined to see if the particle is stable or only a transient particle which will break up into other particles. The life-times of unstable particles are extremely short, ranging from 10^{-17}s to 10^{-21}s, and it is debatable if a particle which lasts only for 10^{-21}s should be called a particle. Generally now such short-lived particles are called resonances which are produced in an interaction which is only a step to the final product.

Classification of Particles

The rudimentary classification of particles is into four groups:

(1) **Gauge bosons**
(2) **Leptons**
(3) **Mesons**
(4) **Baryons**

All particles have an anti-particle which has the same mass but opposite charge as the real particle, the only exception being the photon, which is its own anti-particle and forms a group on its own. The leptons (electron, muon, and neutrino) form a stable group of particles and do not react to the strong nuclear force. This group of particles, and the photon, are perhaps the most fundamental of all particles. The mesons are unstable particles and (as will be seen later) exist only to act as a means which enables nucleons to interact with each other. They are subjected to the strong nuclear force. All particles heavier than the proton are called baryons, every one of them, except the proton, is unstable in some degree, and a vast number of them are known. Only a few are listed in the Table on the next page.

Mesons and baryons are collectively called hadrons. All of these unstable particles have been detected either in the cosmic flux falling on the earth or produced in the very high energy accelerating machines in Europe, the USA *etc.*

Strangeness

Some particles have long life-times ~10^{-9} s, which is much larger than that encountered normally. Particles which possessed these long life-times were called "strange". Strangeness describes not a new property of matter but a different quality of matter which persists long enough to enable that particle to engage in strong nuclear-force interactions. Hence strangeness does not persist indefinitely. The decay of a strange particle into other particles with the abolition of strangeness proceeds via the weak nuclear force. The strange (and doubly strange) particles form highly symmetrised shapes when combined with non-strange particles. The pattern itself does not explain anything, but the underlying theory, known as Group Theory, does indicate by symmetry arguments which particle should be necessary to form a complete group. This mathematical procedure had a resounding success when it predicted the existence of a triply strange particle known as "omega minus". The organisation of particles according to properties of mass, spin, and strangeness in groups is now only an organisation exercise, and it will not tell us anything about the composition of nucleons.

Interactions of Particles

The method by which atomic, nuclear, and sub-nuclear particles interact is via the exchange of energy which can be considered as a particle exchange. The interaction between electric charges proceeds by the exchange of photons. For example, two charges feel each other by one charge emitting a photon which interacts with the second charge. Since the electric force has infinite range, its force-carrying particle has zero mass. The same criteria apply in the gravitational force, where the graviton is the particle which carries the force effect between particles of matter. Since the weak and strong forces are short-range, then their force-carrying particles have finite masses. The weak force is transmitted by W and Z particles and the strong force can be considered as transmitted by mesons. The quarks also interact via the strong force, here carried by gluons (mass at present unknown), which also feel the force themselves. Strangeness is conserved in strong nuclear reactions but not in weak ones.

A theory which combines the electric and weak forces into a single interaction has predicted the masses of the W and Z particles to be around 82 and 93 GeV respectively. Back in 1983 experimental evidence was found by international groups at CERN for the existence of the W particle with the predicted mass thereby giving considerable support to this theory. A long term aim is to unify all the known forces of nature into a single interaction.

Quarks

The stability of the leptons contrasts sharply with the instability of the hadrons (excepting the proton), and this as well as other things had led physicists to consider that all hadrons were composed from different combinations of yet undiscovered particles. Gell-Mann first postulated the existence of three particles from which the nucleons, mesons, and hence all hadrons are composed. These "new" particles are attributed with fractional electric charges of $+\frac{2}{3}$, $-\frac{1}{3}$, and $-\frac{1}{3}$ of the electron charge. The particles were called quarks. The name quark was taken from the novel *Finnegans Wake* by James Joyce, the meaning of which is obscure, which is perhaps appropriate, but as students of Joyce will know, quark means "non sense", and other interpretations as to its meaning, such as the "sound of seagulls" or "quarts" are wrong. The three quarks were called up, down, and strange and

SOME MEMBERS OF THE ATOMIC FAMILY

The numbers in brackets after the name denote first the electric charge and second, the mass. The charge on an electron is counted as −1 unit and the electron mass as +1 unit. Thus (+1,207) means the particle has a positive charge of 1 unit and a mass 207 times that of the electron.

The mass energy of an electron is 0·51 MeV, hence conversion to mass energies can be made by multiplying the given mass by 0·51. Thus the muon has a mass energy of 106 MeV. Note: the letter M is used to denote quantities of millions and the letter G to denote quantities of thousand of millions.

Photon (0, 0)	A quantum of electromagnetic radiation, *e.g.*, light, X-rays, γ-rays. The concept was introduced by M. Planck in 1900 when he described the emission of light as taking place in "packets" rather than in a steady stream. The energy of a photon is proportional to the frequency of the radiation and inversely proportional to the wavelength.
	Leptons
Electron (−1, 1)	Discovered by J. J. Thomson in 1897. The number of orbital electrons in an atom determines its chemical properties. Actual rest mass = $9{\cdot}1 \times 10^{-28}$ g. Emitted as β-rays by some radioactive nuclei. A stable particle.
Positron (+1, 1)	Positive counterpart or, "anti-particle", to the electron. Predicted theoretically by P. A. M. Dirac in 1928 and first discovered in cosmic rays by C. D. Anderson in 1932. Emitted as β-rays by some radioactive nuclei. When positrons and electrons collide they usually annihilate each other and turn into γ-rays; consequently, positrons only last about 10^{-10} sec. within ordinary matter, but are stable in isolation.
Neutrino (0, 0) and **Anti-neutrino** (0, 0)	These particles travel with the speed of light and are distinguished from one another by the relation of their spin to their direction of motion. A neutrino is emitted with the positron during positive β-decay; and an anti-neutrino with the electron during negative β-decay. Their interaction with matter is extremely slight. First postulated by Pauli in 1933 and detected in 1956. π-meson decay also produces neutrinos and anti-neutrinos but in 1962 it was proved experimentally that these are a different species. Thus there are two kinds of neutrino each with an anti-neutrino. All these particles are distinguished from photons by having different spin.
Muon (±1, 207)	Similar to, but heavier than, the electron and positron; disintegrates into electron (or positron if positive) + neutrino + anti-neutrino.
	Mesons
Pion (±1, 273) or (0, 264)	The π-meson. Charged pions decay either into muons and neutrinos or into electrons and neutrinos. Neutral pions decay into γ-rays, into "positron-electron pairs", or both. Pions are intimately connected with nuclear forces, *i.e.*, with the "strong" interaction.
Kaon (±1, 966) or (0, 974)	The K-mesons. These decay in many different ways producing other mesons, electrons, and neutrinos.
	Baryons
Proton (+1, 1836·1)	The positively-charged constituent of nuclei; the hydrogen nucleus is one proton. Fast-moving protons occur in cosmic rays. Does not spontaneously disintegrate.
Anti-proton (−1, 1836·1)	Negative anti-particle of the proton. Its existence was long suspected. Artificially produced and detected for the first time in 1955. Will react with the proton to produce pions or kaons.
Neutron (0, 1838·6)	Discovered by J. Chadwick in 1932. The neutral constituent of nuclei. When free it spontaneously disintegrates into a proton, an electron, and an anti-neutrino, after an average lifetime of about 18 minutes. Passes through matter much more easily than charged particles.
Anti-neutron (0, 1838·6)	The anti-particle of the neutron from which it is distinguished by properties connected with its magnetic moment and spin. Will react with neutron to produce pions or kaons.
Lambda Particle (0, 2183)	Discovered in 1947. Decays into proton plus pion.
Sigma Particle (0 or ±1; about 2330)	Various modes of disintegration, producing neutrons, protons, mesons and lambda particles.
Omega Particle (±1, 3272)	Predicted by scientists and duly discovered at Brookhaven, New York, in 1964.
Psi Particle (0, about 6100)	Discovered independently by two laboratories in the USA 1974.

have the properties given in the Table below:

Name	charge	spin	mass-energy (MeV)
up	$+\frac{2}{3}$	$\frac{2}{3}$	336
down	$-\frac{1}{3}$	$\frac{1}{2}$	338
strange	$-\frac{1}{3}$	$\frac{1}{2}$	540

These particles interact with each other via the strong force. Hence it can be seen that by taking different combinations of quarks, different hadrons can be built up. For example, the proton is two up quarks and one down, the neutron is two down and one up. The simplicity of this system can be appreciated, but the only experimental evidence to support the existence of quarks is indirect.

No one has yet isolated a single quark! Many scientists are seeking ways to produce and detect them, but as of now no claims have stood the test of scrutiny. Further theoretical and experimental evidence has proved the existence of three more quarks, known as top, bottom and charmed (*see below*). These six elementary particles are complimented by six equivalent anti-matter particles, each with the opposite charge of its mate.

The K-mesons, for example, are composed of a quark and an anti-quark either with the spins of the two quarks aligned parallel to give a net spin of one, or aligned antiparallel to give a net spin of zero. The charges +1, −1, and 0 are simply determined by selecting the correct combination of up and down quarks.

Charm

In the quest to unite the weak and electric forces, theoreticians were forced to introduce yet another new particle into the quark family. This was a charmed quark with charge $+\frac{2}{3}$. The four members of the quark family had seemed then to be symmetrical with the four members of the lepton group (electron, muon, and two neutrinos). Since the charmed quark had charge $+\frac{2}{3}$ and mass of 1,500 MeV, it could simply replace the up quark as a building brick in nucleons to produce charmed matter. For example, by replacing the up quark in a proton and a meson by a charmed quark we get a charmed proton and a charmed meson. The first experimental evidence of the existence of charm was obtained by the high-energy physics group at University College, London, working at CERN laboratory, when they established the existence of "a neutral current interaction" in neutrino scattering experiments. Although "naked" charm has never been detected, charmed mesons (masses of 1,865 and 2,020) have been detected by the SPEAR laboratory in USA and charmed anti-protons have also been detected with masses of 2,260 MeV. The experimentally determined masses are in sufficient agreement with theory to confirm the existence of the charmed quark. Theoretical proof for the existence of two more quarks, top and bottom, soon followed and by 1995 both had been discovered by experimentalists.

As a whole, this theory of elementary particles is called the standard model and has become generally accepted. Scientists are not happy to rest with this, however, because the number of unspecified parameters involved (the standard model has about 20 of these) seems too many for a fundamental theory. The search is on for deeper patterns and symmetries to explain matter.

The Higgs Particle

Since the discovery of the top quark, physicists have concentrated their efforts on tracking down an even rarer particle called the Higgs. Finding it would not only continue to validate the standard model, but would also help theorists explain the existence of mass. Since the US government decided to stop funding its expensive Superconducting Supercollider project, the search is wholly in the hands of the Europeans at CERN.

In July 2012 CERN finally confirmed the existence of the Higgs.

QUANTUM THEORY AND RELATIVITY

In our discussion of the nature of the various particles in physics we have alluded to them as being classified with well-defined sizes and weights. Of course, once we consider the physics of matter on a scale which is smaller than that of our everyday comprehension, then the classical physics of Newton is insufficient and we must use quantum physics. In the atomic region of reality we are again faced with the problem of indivisibility where the Greeks stopped their thinking and called the smallest particles of the universe atoms.

Today we know that each separate particle is composed of a definite amount of energy, and the larger the particle, *i.e.*, the more energy it is composed of, the easier it is to detect. We also know that the exchange of force between nucleons is carried by particles and that this inchangeability between mass and energy is a reality of quantum theory. To see this more fully we must realise that quantum theory rests on the theory of measurement! If a particle, of any type or structure, is composed of an amount of energy ΔE, then it is necessary to make measurements on it for a certain minimum time before it is detected. This minimum time Δt is given by the equation $\Delta E \times \Delta t\ \hbar$, where $\hbar$ is Planck's constant divided by 2π; hence it can be seen that the smaller ΔE, then the longer a measurement must be made to detect the particle.

Correspondingly, the time of measurement itself introduces an uncertainty, ΔE, in the energy of the particle. As well as the parameters ΔE and Δt, a particular physical event can be expressed in terms of its momentum p and position q, and these can also be expressed in a relationship as $\Delta p \times \Delta q \geq \hbar$. Hence one can ask at what position in space, q, is a particular particle with momentum p? Or what exactly is the wavelength of a wave? It may be thought that the first question cannot reasonably be asked of a wave nor the second of a particle, but bearing in mind the dual roles of particles and waves discussed earlier, then these questions can be interchanged.

The Heisenberg Uncertainty Principle

We know that electrons behave both as particles and waves. Since electrons have something in common with both, one question cannot be answered precisely for electrons without ignoring the other; alternatively, both questions can be given an imprecise answer. As the wavelength of electrons is intimately connected with their speed, one has to accept an accurate knowledge of the speed (wavelength) and ignorance of position, or the converse, or *inaccurate* knowledge of both. This is the famous Heisenberg Uncertainty Principle.

Quantum theory is a set of mathematical rules for calculating the behaviour of fundamental particles in accordance with the Uncertainty Principle. In spite of its equivocal-sounding name, the principle has led to an enormous increase in the accuracy with which physical phenomena can be described and predicted. Quantum theory includes all that previous theories did and more.

Quantum theory grew up in the same epoch as the Theory of Relativity. Heroic attempts have been made to combine the two, but with only partial success so far. Relativity is concerned with all motion and all physical laws, but its characteristic manifestations occur only when something is moving with nearly the velocity of light. Quantum theory is likewise all-embracing, but its typical phenomena almost always occur when something on the minute atomic scale is in question. Consequently, the vast majority of everyday mechanics needs no more than the classical theory laid down by Newton, which is neither relativistic nor quantum.

Relativity

Historically, relativity grew out of attempts to measure the speed with which the earth moved through that hypothetical medium called the ether, which was supposed at that time to be the bearer of light waves. To take a simple analogy: sound waves travel through still air with a certain definite speed, v. If you move through the air with speed v' towards oncoming sound waves, they will pass you at the speed $v + v'$. Michelson and Morley, in their celebrated experiment of 1887, failed to find the corresponding behaviour on the part of light. This is so important an experiment that it has been repeated, and repeatedly discussed ever since. In October 1958 the latest and most accurate confirmation of the Michelson–Morley result was announced. It seems as if light always travels with the same speed relative to an observer, however fast he moves relative to anything else. Einstein put it this way: two observers moving with any constant velocity relative to each other will always agree that light travels past them at the same speed; this speed is denoted by c, and is approximately 186,000 miles per second.

It should be remembered that the limiting value of the velocity of light in relativity is a postulate introduced by Einstein not a conclusion which the theory provides. There may exist forms of matter which can travel faster than light!

Nevertheless, the postulate that the maximum velocity encountered in the universe is c, logically developed, leads to remarkable conclusions. For instance: if you walk from tail to nose of an aircraft at 4 mph and the plane is receding from me at 300 mph, then you recede from me at 304 mph “Common sense”, Newton, and Einstein would all agree on this. But if you could walk at 0·25c and the plane moved at 0·5c, the Newtonian mechanics would give your recession speed as 0·75c, whereas Einsteinian relativity would give about 0·67c.

Although at the everyday speed of 300 mph, the disagreement, though present in principle, is absolutely negligible, at speeds near that of light it is very pronounced. Many experiments show that the relativity answer is right.

Equivalence of Mass and Energy

The most famous consequence of relativity theory from which we derive benefit is the knowledge that mass can be converted into energy. The amount of energy, E, which can be derived from a given mass, m, of any type of material is given by the celebrated equation $E = mc^2$. If we take one gram of ash and convert it into the free energy of which it is composed we would get 10^8 kilowatts of power, sufficient to heat 15 houses for a year. The heat provided by the material which produced the ash is equivalent to that obtained from burning a single match. The massive energy released by $E = mc^2$ has been demonstrated in the power of nuclear weapons, but this energy has also been put to peaceful uses in nuclear-powered electricity generating stations.

In fundamental particle physics the masses of particles were always expressed in units of mass energy using $E = mc^2$ as the conversion equation. This is a matter of convenience from the realisation that mass is simply a condensed form of energy. The mesons which are the force-exchanging particles in the strong interaction have a mass energy of approximately 130 MeV, which is equivalent to a real mass of only 210^{-26} grams. The energy of the sun is provided by the conversion of real mass into light energy through thermonuclear fusion processes.

Mass and Rest Mass

The concept of mass is not a simple idea to grasp, for as we have seen, the mass of a body which is at rest is equivalent to its inherent latent energy. Further complications and interpretations arise when the body starts moving and its mass is no longer necessarily a constant quantity.

A stationary body can be observed to have a mass called its *rest mass*. If the body moves, it has energy of motion and therefore, according to Einstein's mass–energy equation, it increases its mass.

Mass thus depends on speed, but in such a way that there is very little change unless the speed approaches that of light. Many experiments on atomic particles demonstrate this. The interesting question now arises: do all fundamental particles have rest mass? or do some have mass derived solely from their energy? The answer appears to be that photons and neutrinos have no rest mass; all other particles have. The Table on **T16** gives their rest masses.

Special Theory of Relativity

The mathematical development of Einstein's ideas, leading to the conclusions just referred to, constitutes the Special Theory of Relativity. Stated more generally, the theory raises the question whether two observers in uniform relative motion could ever detect, as a result of their relative speed, any difference in the physical laws governing matter, motion, and light. To this, Special Relativity answers: No. The detailed theory involves special consideration of the results the two observers would obtain when measuring (i) the spatial distance, and (ii) the time interval, between the same two events. It turns out that they would not agree on these two points. They would agree, however, on the value of a certain quantity made up jointly of the spatial distance and the time interval in a somewhat complex combination. The intimate mixture of space and time in this quantity has led to the treatment of the three space dimensions and time on an equivalent footing. Hence the frequent references to time as the “fourth dimension”. Scientists have devised an extremely elegant presentation of relativity theory by using an extension of ordinary geometry to four dimensions. A line drawn in his four-dimensional space represents the path of a particle in space and time, *i.e.*, the whole history of the particle. Thus the movement of particles in the ordinary world is turned into the geometry of lines in Minkowski's four-dimensional world of “space–time”.

General Relativity and Gravitation

In 1915, 10 years after the publication of the Special Theory of Relativity, Einstein published his theory of General Relativity. This apparently innocuous extension of the ideas of special relativity to include accelerated relative motion opened up new and difficult fields of mathematical complexity which, when solved, enabled Einstein to include gravitation in the theory. In discussing the physics of atomic, nuclear, and subnuclear particles, we did not include the effect of the gravitational force, since in relation to the Electric, Weak and Strong forces it is extremely small and can be neglected in the discussion of the structure of matter but not in the discussion of astronomical problems and the movements of large-scale electrically uncharged bodies.

It has been usual, ever since Newton, to say that two bodies of mass m_1 and m_2, separated by a distance r attract one another with a force proportional to m_1m_2/r^2. This is Newton's inverse square law of gravitation which explains the movements of planets and comets and the falling to earth of an apple from a tree.

A Uniform Gravitational Field

The apple's fall is accelerated, and we observe this by noting its position relative to certain marks fixed with respect to us, and by timing it with some sort of clock. This system of location in space and time may be called our “frame of reference”. We therefore assert that, in our frame of reference, the apple falls down with an acceleration which Newton saw no alternative but to attribute to a thing called gravitational attraction. Galileo had shown that *all* bodies fall with the same acceleration at all points, and we can now rephrase this by saying that in our frame of reference there is a constant gravitational attraction or *uniform gravitational field*.

Now suppose a collection of falling bodies is observed by us and an intelligent creature, designated C, inhabits one of them. C has his own frame of reference fixed relative to him and we have ours fixed relative to us. In *C*'s frame neither his own body, nor any of the others, is accelerated, and therefore he has no reason to suppose a gravitational force is acting on them. We have, therefore, the following situation:

> (i) in our frame, fixed relative to us, we find all the bodies falling subject to a gravitational pull;

(ii) in *C*'s frame, undergoing accelerated fall relative to us, no gravitational field is apparent to *C*.

It looks, therefore, as if one has only to choose the correct frame of reference for the measurements in order to remove the need for any assumptions about the existence of gravitational fields. This is a simple illustration of the connection between gravitation and frames of reference for the measurement of space and time. Einstein's General Theory of Relativity extends this to cover non-uniform gravitational fields and shows that what Newton taught us to call the gravitational field of material bodies is better thought of as a peculiarity of the space and time in the neighbourhood of such bodies. Since space–time, as we mentioned above, can be expressed in geometrical terms, Einstein has transformed the theory of gravitation into an exercise in the geometry of space–time. Other physicists, in Einstein's tradition, are trying to turn *all* physics into geometry, but no one knows whether this is feasible.

All this abstruse work is much more than a demonstration of mathematical power and elegance. Observable phenomena which fall outside the scope of Newton's theory of gravitation are accounted for by relativity. One is the small but definite discrepancy between the actual orbit of the planet Mercury and the predictions of Newton's theory. Another is the effect of a gravitational field on the wavelength of light emitted by atoms. Similar atoms in different places in a gravitational field emit radiations with slightly different wavelengths. For example, the light from an atom in the intense field of a star should have slightly longer wavelength than the corresponding light from an atom on earth. This effect has always proved very difficult to detect with certainty. However, Einstein's prediction was verified back in 1960.

Quantum Theory and Relativity Combined

The atomic family table refers to "antiparticles". The theory which first introduced such things in 1934 is due to the Cambridge physicist Dirac and was epoch-making. Dirac conceived an equation to describe the motion of electrons subject to the laws of both quantum theory and relativity. His achievement was thus to synthesise these two great ideas. The spin of the electron was originally a supposition that helped to make sense of spectroscopic observations of light emitted from atoms. Dirac's equation made spin a logical consequence of the union of relativity and quantum theory. Perhaps even more important was the brilliant inference that the equation for the electron implied the existence of another particle having the same mass and spin but with a positive instead of a negative electric charge. This object is called the electron's antiparticle and is now well known as a positron.

Every particle is now believed to imply an antiparticle, so it is conceivable that the universe could have been (but isn't) an anti-universe, *i.e.*, all the electrons and protons might have been positrons and antiprotons and so on. The laws of physics would still have been applicable, however.

The gravitational force has an infinite range and therefore its force-carrying particles must travel at the speed of light. The graviton is the name of the particle which transmits the gravitational force between bodies with mass. No experiment has yet found the existence of gravitons which are the postulated quanta of gravitational waves. There is an exact analogy between photons, the quanta of electro-magnetic radiation, and gravitons.

Conservation Laws

If charged particles interact, then it is found that the amount of electric charge existing after the reaction is the same as that which existed before the event. This is called the law of the conservation of charge. Many other conservation laws exist in physics, *e.g.*, conservation of mass energy, angular momentum, linear momentum, and other more abstruse conservation laws exist in particle physics, *e.g.*, conservation of baryons, leptons, strangeness, isotopic spin, and parity. The last three conservation laws listed have been found to have a limited jurisdiction, and the violation of parity in the weak interaction was a great surprise to physicists.

Any reader who looks in a mirror knows that the left- and right-hand sides of his face are interchanged in the image. Fortunately mirrors do not also turn the image upside down, but, if they did, the face would then have undergone what is called "a parity transformation". A screwdriver driving a right-handed screw downwards becomes, on parity transformation, a screwdriver driving a left-handed screw upwards. The law of conservation of parity is a way of asserting that any physical process that goes on in the world could equally well go on—obeying the same laws—in a parity transformed world. There is nothing left-handed that does not in principle have a right-handed counterpart.

Conservation and Parity

It came as something of a shock when, in 1957, after theoretical proposals by Lee and Yang in America, Wu and co-workers proved that parity was not always conserved. To understand Wu's experiment, we must recall that nuclei can have intrinsic spin. Suppose the axis of spin were downwards into the page and the rotation were suitable for driving an ordinary screw into the page. Then Wu showed that beta-rays from such a nucleus are emitted *preferentially upwards*, *i.e.*, against the direction of travel of the screw. The parity transformed version of this would have the beta-rays preferentially emitted in the same direction as the travel of the screw and, if parity is conserved, this process would happen too. But it does not. If the beta-rays in the experiment had been emitted in equal numbers up and down, then the parity transformed version would have had this feature too (thus conserving parity).

A reprieve for the standard model came when P symmetry was combined with a transformation of charge. But when this new CP symmetry was also found to break down, scientists were forced back to their accelerators to search for either another patch to, or an alternative for, the standard model.

Conclusion

Over a century's development of the atomic ideas has brought a progressive, if jerky, increase in the mathematical precision of the theories. In some fields of particle physics, observations to one part in a million, or even better, can be explained, to that level of accuracy, by the existing theories. At the same time, however, the theories have lost visual definition. An atom as an invisible but none the less solid billiard ball was easy enough; so was a light wave conceived like a sound wave in air. Even after Rutherford, an atom consisting of a miniature solar system merely exchanged the solid billiard ball for a system of revolving billiard balls and was no great obstacle to visualisation. But since quantum theory and the Uncertainty Principle, every unambiguous visualisation of fundamental wave-particles leaves out half the picture, and although the electrons are in the atom, we can no longer represent them in definite orbits. The moral seems to be that visualisation is unnecessary, or at best a partial aid to thought.

THE PROPERTIES OF MATTER IN BULK

One of the most obvious and at the same time most wonderful things about the properties of matter is their great variety. Think of air, diamond, mercury, rubber, snow, gold, pitch, asbestos *etc*. Even the differences of state of the same chemical substance are remarkable enough, ice, water, and steam, for example. One of the aims of physics is to reach an understanding of all these different properties by explaining them in terms of the behaviour of the particles discussed in the previous section.

The great success with which this imposing programme has been carried out indicates the maturity of physics. It is difficult to think of any major property of matter in bulk for which there is not some attempted theoretical explanation, though future physicists will no doubt regard some present-day theories as rudimentary or incorrect.

Physics, Statistics, and Thermodynamics

Take a number equal to the population of London, multiply it by itself, and multiply the product by another million. The answer is about the number of molecules in 1 cubic centimetre of ordinary air. They are constantly moving about and colliding with one another. Even if the nature of the molecules and their laws of motion were perfectly understood, it would clearly be impracticable to calculate the exact paths described by each particle of so vast an assembly. This difficulty brought into being a whole branch of physics concerned with calculating the overall or average properties of large numbers of particles.

Just as statisticians will provide the average height, income, expectation of life, and so on, of the population of London, without knowing everything about every individual, so statistical physicists can work out average properties of molecules or atoms in large groups. This important branch of physics is called *Statistical Mechanics*. It was founded in the nineteenth century by Maxwell, Boltzmann, and Gibbs and is still being actively developed.

Consider now all the molecules in 1 cubic centimetre of air contained in a small box. They are continually bombarding the walls of the box and bouncing off. This hail of impacts (it is actually about 10^{23} impacts per square centimetre per second) is the cause of the pressure which the gas exerts against the walls of the box. Now suppose we pump air in until there is twice as much as before, though the box is still the same size and at the same temperature. This means that the density of the gas (*i.e.*, the mass of 1 unit of volume) has doubled. We should now expect twice as many impacts per second on the walls as before, and consequently twice the pressure. We therefore arrive at a conclusion that, if the volume and temperature are constant, the pressure of a gas is proportional to its density.

This is one of the simplest statistical arguments that can be checked against observation; in fact, it stands the test very well.

Heat, Temperature, and Energy

The proviso about the temperature remaining the same is an important one for the following reason. In the nineteenth century there was much discussion about the nature of heat. To Joule we owe the now well-established view that heat is equivalent to mechanical work. In one of his experiments, in the 1840s, the work necessary to rotate paddle wheels against the resistance of water in a tank generated heat that caused a slight rise in the temperature of the water. Joule found out exactly how much work was equivalent to a given quantity of heat.

However, one can do other things with work besides generating heat; in particular, work creates motion, as when one pushes a car. Bodies in motion possess a special form of energy, called kinetic energy, which is equal to the work done in accelerating them from a state of rest. We have, then, three closely connected ideas: work, heat, and kinetic energy. Now according to the views of the nineteenth century, which are still accepted, any heat given to a gas simply increases the kinetic energy of its molecules; the hotter the gas, the faster its molecules are moving. If, therefore, the gas in our box is allowed to get hotter, there is an increase in molecular speed, and the impacts on the walls become correspondingly more violent. But this means the pressure increases, so we have another law: if the density remains the same, the pressure increases if the temperature does.

Laws of Thermodynamics

Such considerations as these have been pursued with great elaboration and subtlety. The notions of heat, temperature, energy, and work—familiar but vague in everyday life—have been given precise definitions, and the relations between them have been enshrined in the Laws of Thermodynamics. Enshrined is perhaps a suitable word, because these laws are so soundly and widely based on experimental results that they have greater prestige than any others in physics. If any proposed physical law comes in conflict with thermodynamics then so much the worse for that law—it has to be revised.

It is sometimes asserted that no one is properly educated who does not understand the Second Law of thermodynamics. We cannot, therefore, leave this section without at least stating the two best known thermodynamic laws:

First Law: *If any physical system is given a quantity of heat, and if the system performs some work, then the energy of the system increases by an amount equal to the excess of heat given over work done.* This law asserts that heat, energy, and work are convertible one into the other, and that all such transactions balance exactly. This is one form of a principle accepted as fundamental in all science, *viz.*, the Principle of the Conservation of Energy, according to which energy can never be created or destroyed, but only changed from one form to another.

Second Law: *It is impossible to make an engine which will continuously take heat from a heat source and, by itself, turn it all into an equivalent amount of mechanical work.* In fact, all engines which produce work from heat—steam engines for example—always use only a fraction of the heat they take in and give up the rest to some relatively cool part of the machine. The Second Law makes this obligatory on all work-from-heat devices. This statement of the Second Law has an engineering ring about and, indeed, it arose from the work of the nineteenth-century French engineer Carnot. Nevertheless, it can be rephrased in terms of the concept of *entropy*, and has been applied with unbroken success to all fields of science involving the transfer of heat and allied matters. It sets a definite limit to the kinds of physical and chemical process that can be conceived to take place. Nothing has been known to contravene it.

The States of Matter

The molecular motion in gases has been referred to in the previous section. Tacitly it was assumed that each molecule acted independently of all others, except that collisions occurred between them. In reality, molecules exert attractive forces on one another and, if a gas is cooled so that molecular movements become relatively sluggish, a time comes when the attractive forces succeed in drawing the molecules close together to form a liquid. This process is called condensation.

The molecules in a liquid are packed tightly together and they impede each other's movements. On the other hand, movement still persists, and the molecules struggle about like people in a milling crowd. Besides wandering about, the molecules vibrate. These motions represent the energy contained in the liquid.

The fact that the molecules, though irregularly packed, can still slip past one another and move from place to place, explains the essential property of liquids that distinguishes them from solids—ability to flow. As a matter of fact, although the rather vague assertion that in a liquid molecules are irregularly packed would be generally accepted, there is no agreed opinion on what the irregularity is actually like. Indeed, not only the precise structure of liquids, but the theory of liquids in general, is fraught with such considerable mathematical difficulties that the liquid state is much less well understood than the solid or gaseous.

Most solids are crystals. The popular idea of a crystal is of something which has a more or less regular geometrical form with faces that shut in the light—like snowflakes or gems. However, crystallinity really depends on a regular inner pattern of the atoms, and may or may not show itself on the visible surface. A lump of lead, for example, is crystalline, despite its appearance.

The actual arrangement of the atoms in a crystal can be extremely complex. Some are quite simple, however. The largest model of a crystal structure must surely be the 400-ft. "Atomium" building in the 1958 Brussels Exhibition. This consisted of eight balls, representing atoms, situated at the corners of a cube, and one more ball exactly in the middle. Imagine this repeated in all directions so that every ball is the centre of a cube whose corners are the eight neighbouring balls. This is known to crystallographers and physicists as the "body-centred cubic structure"; it is the actual arrangement of atoms in iron, sodium, chromium, and some other metals. If every ball, instead of being the centre of a cube, were the centre of a regular tetrahedron (a solid figure with four equal triangular faces), and had its four neighbours at the corners of the tetrahedron, then we should have the "diamond structure". This is how the carbon atoms are arranged in diamonds.

In crystals the atoms are locked into a regular ordered structure by attractive forces which give the solid its rigidity and prevent it from flowing. The atoms are so close together that any attempt to press them closer involves crushing or distorting the atoms—a process they resist strongly. This explains why solids (and liquids too) are so difficult to compress. Gases can easily be compressed because there is so much space between the molecules.

Distinction of Solid and Liquid

The distinction between solid and liquid is not so sharp as is commonly supposed. A lump of dough will not bounce, but is plastic; a steel ball-bearing is very elastic and bounces excellently, but one cannot mould it in the fingers. Neither dough nor steel qualifies for description as a liquid. There are, however, substances which can be moulded like plasticine into a ball that will then bounce very well on the floor like an elastic solid, and finally, if left on a flat table, will spread into a pool and drip off the edge like a liquid. There is no point in trying to force such things into rigid categories. One may say instead that for short, sharp impacts the material behaves like an elastic solid, but under long-sustained forces it flows like a liquid. The properties of these, and many other anomalous materials, are increasingly engaging the attention of those who study the science of flow—*rheology*.

It is interesting to see how many familiar and important materials exhibit peculiar rheological behaviour—paint, dough, ball-pen ink, cheese *etc*.

Inside a Crystalline Solid

We now return to our wallpaper analogy. Suppose we have walls papered with a regular pattern of, say, roses, fuchsias, and green leaves. These represent the different kinds of atoms in the solid. Careful observation shows that the whole pattern is shimmering. The flowers and leaves are not stationary, but are undergoing slight random oscillations about their proper positions. In a crystal these movements are called thermal vibrations, and are never absent. The hotter the crystal, the more the vibration, and at a high enough temperature the vibrations become so great that the atoms get right out of position and the pattern disappears altogether, *i.e.*, the crystal melts. Thermal vibrations are essential to the theory of solids, and are responsible for numerous physical properties.

Next we note something extraordinary about some of the papered walls. On these the paper has been hung in irregular patches fitted together like a not very well-made jig-saw puzzle. Lines of roses which should be vertical are horizontal in some patches, oblique in others. This represents the situation in most ordinary solids, for they consist of many small pieces of crystal irregularly packed together.

Such material is called *polycrystalline*, and the small pieces are *crystal grains*. Crystal grains may be almost any size, sometimes visible to the naked eye, as often on galvanised iron.

However, on one wall, we see excellent regularity and no obvious patches at all. The physicist would call this a *single crystal*, and several techniques exist for preparing them. Natural single crystals can be found, and there are some beautiful large single crystals of rock salt. But on examining the single crystal wall closely, we find a number of places where the paperhanger has failed to make adjacent pieces register perfectly—there is a slight disjointedness. This occurs in real single crystals, and the line along which the structure fails to register is called a *dislocation*. These are much studied by physicists because of their bearing on the mechanical properties of solids, on the yielding of metals under strong stress, for instance.

Types of Impurity

This by no means exhausts the possibilities of the wallpaper analogy; several other phenomena can be found. For example, in a place where there should be a fuchsia there is actually a daffodil—something completely foreign to the pattern. Or perhaps a small wrongly shaped leaf is jammed between the proper leaves in a place that should really be blank. These represent chemical impurity atoms. The first is called *substitutional*, because it occupies the position of an atom that should be there, the second is called *interstitial*, because it does not. Substitutional impurities of indium metal, deliberately added to the semi-conductor silicon, make possible the manufacture of transistors (*see* **Section L**). Some steels derive their valuable properties from interstitial carbon atoms within the iron pattern.

What physicists call a vacancy would occur if a flower or leaf were simply missing. Remembering that all the atoms are vibrating, we should not be surprised if occasionally an atom jumps into a neighbouring vacancy if there happens to be one, *i.e.*, the atom and the vacancy change places. Later this may occur again. In the course of time, a rose which was near the ceiling may make its way to the floor by jumping into vacant rose positions when they occur near enough. This process, which the physicist calls *diffusion*, is also analogous to the game in which numbers or letters can be moved about in a flat box because there is one vacant space to permit adjustment. The more vacancies there are in a crystal, the faster diffusion occurs. It is very slow in solids, but is nevertheless evidence that apparently quiescent materials are really internally active.

Metals, Electricity, and Heat

There is ample evidence that inside metals there are large numbers of free electrons. To illuminate this statement let us take sodium metal as an example. One single sodium atom has a nucleus with eleven protons; there are therefore eleven electrons in the atom. The outermost one is easily detached, leaving a positively charged sodium ion behind. We may think of these ions arranged in the three-dimensional pattern characteristic of sodium crystals. It is the same as the iron structure previously described. The detached electrons, one per atom, occupy the spaces in between. The usual metaphor is that the structure of ions is permeated by a "gas" of electrons. Like all visualisations of fundamental particles, this must be taken as a rough approximation. The important point is that the electrons in the gas are not bound to individual atoms but may wander freely about the crystal, hindered only by the collisions they make with the vibrating ions.

This is the picture as it appeared to physicists of the first decade of the 20th century, and we can explain many properties of metals with it. Naturally the theory has developed greatly since then, thanks to the great work of Lorentz, Sommerfeld, and Bloch; it now relies heavily on quantum theory, but it is surprising how little violence is done to modern ideas by the simple picture we are using.

The free electrons move randomly in all directions at thousands of miles per hour. If the metal is connected across a battery it experiences an electric field. Electrons are negatively charged particles, and are therefore attracted to the electrically positive end of the metal. They can move through the metal because they are free; this flow is not possible to those electrons which remain bound to the ions. The function of the battery is to keep the flow going and, for as long as it is going, it is the electric current.

The flow of electrons is not unimpeded. They constantly collide with the ions and are deflected from the path of flow. This hindrance is what the electrician calls *electrical resistance.* The electric force, due to the battery or a dynamo, accelerates the electrons, thus giving them extra energy; but they lose this to the ions at collisions because the ions recoil and vibrate more than before. The net effect of innumerable collisions is to increase the thermal vibrations of the ions, *i.e.*, to make the metal hotter. This is the explanation of the fact well known to every user of electric irons; that electric current heats the conductor. If a strong current is passed through a wire, the heating is so great the wire glows, as in light bulbs, or melts and breaks, as in blown fuses.

If one end of a metal rod is heated we soon feel the heat at the other end; metals are excellent thermal conductors. This is because the mobile free electrons carry the heat energy down the rod, passing it on to the ions by colliding with them. Substances without free electrons cannot do this, nor can they conduct electricity well; we have, in the free electrons, an explanation of the fact that the good electrical conductors are the good heat conductors. For technical purposes, it would be useful to have electrical insulators that would conduct heat well, and *vice versa*; but this is almost a contradiction in terms, and one can only compromise.

Non-Conductors and Semi-Conductors

There are some elements, and numerous compounds in which all the electrons are so tightly bound to their parent atoms that free electron flow is impossible. These materials are electrical and thermal insulators.

Let us return to our sodium atom. It readily loses its outer electron, forming a positive ion. The ion is very stable; indeed, its electron arrangement resembles the "closed shell" belonging to the inert gas neon. The chlorine atom, on the other hand, would have a very stable structure, resembling the inert gas argon, if only it could be given one extra electron to complete the closed shell. If the outer sodium electron were given to a chlorine atom we should have two stable ions, one positive and one negative. These would then attract each other and form a compound. This is just how common salt, sodium chloride, is formed, and its crystals consist of a regular network of alternate sodium and chlorine ions. As all the electrons are bound to ions, it is not surprising that salt will not conduct electricity or heat to any appreciable extent. Not all insulating compounds are built on this pattern, but all have structures which bind the electrons tightly.

We saw earlier that Nature does not permit a hard-and-fast distinction between solids and liquids; nor does she between conductors and insulators. Back in the 19th century, Faraday knew of substances which would conduct electricity, but rather badly. A common one is the graphite in pencils. Others are the elements selenium, germanium, and silicon, and a considerable number of compounds. These are called semi- conductors.

The Properties of Semi-Conductors

Semi-conductors conduct badly because they have so few free electrons, many thousands of times fewer than metals. In very cold germanium—say, 200 degrees below freezing—all the electrons are tightly bound to atoms and the substance is an insulator. It differs from normal insulators in that, on warming it, the gradually increasing thermal vibration of the crystal detaches some of the electrons, for they are only moderately tightly bound. The warmer the crystal becomes, the more of its electrons become detached and the better it conducts electricity.

By about the temperature of boiling water, there are so many freed electrons that conduction is moderately good, though less good than in metals. This is basic semi-conductor behaviour. As transistors were made of germanium, and as they were of such great technical importance, more knowledge has accumulated about germanium than about any other material.

Magnetism

The most important thing about magnetism is that it is inseparably connected with electricity. Oersted showed this in July 1820, when he deflected a magnetic compass needle by passing an electric current through a wire near it. Since then, many experiments have shown that wherever a current flows there will certainly be a magnetic field in the surrounding space. The laws of this are very well known now—they are the Maxwell equations previously referred to.

Most people first meet magnetism when they pick up pins with a magnet. Where is the electricity here? What is a magnet?

The explanation of magnetism exemplifies beautifully the technique of explaining the bulk properties of matter in terms of fundamental particles. In the atoms the electrons are moving, and a moving electric charge constitutes an electric current. Therefore each moving electron is a tiny source of magnetism. It does not immediately follow that every atom is a source of magnetism because it might—and often does happen that the magnetic effect of different electrons in the atom cancel out. In helium atoms, for example, the two electrons have equal but opposed magnetic effects. Nevertheless, some atoms and ions have a net effect called their *magnetic moment*. This simply means they behave like tiny magnets. Crystals containing such atoms will be magnetic, though the magnetism is much weaker than in ordinary magnets because the different atoms largely annul one another's effects. In a very limited number of crystals, however, the magnetic ions act on one another in a special way which forces all the atomic magnets to point in the same direction.

Ferromagnetism

The total effect of many co-operating atoms is very strong and the crystal becomes what we normally call a magnet. Iron acts like this, so do cobalt and nickel, the rarer elements gadolinium and dysprosium, and a fair number of alloys. On the whole, this behaviour, which is called *ferromagnetism*, is very rare. The reason for the co-operation of all the atomic magnets is not explained to everyone's satisfaction yet, though the key idea was given by Heisenberg in 1928.

In the section dealing with the electron it was pointed out that every electron has an *intrinsic* magnetic moment. This is in addition to any effect simply due to the electron's motion round a nucleus. The net effects of ions are therefore partly due to the intrinsic magnetism of electrons. In the ferromagnetic metals the latter is by far the most important contribution. Thus we pick up pins, and benefit from magnets in other ways, because innumerable fundamental particles act in co-operation for reasons that are still somewhat obscure. It is interesting to ask whether the electrons responsible for magnetism are the same free electrons that allow the metals to conduct electricity. It is thought not.

We are accustomed to think of magnets as metallic. Nowadays a number of non-metallic magnets are made. They are called *ferrites*, and some are insulators and some are semi-conductors. The combination of magnetism and insulation is technically very valuable in radio, radar, and other applications. The explanation of ferrite behaviour is related to that of metallic ferromagnetism, but is not the same.

Conclusion

The aim of the second part of this account of physics is to show how our conception of fundamental particles allows us to build theories of the properties of matter. This very aim shows that the two "major divisions" of physics referred to at the beginning are divided only in the way that labour is divided by co-operating workers to lighten the task. For the task of physics is a very great one—no less than to explain the behaviour of matter; and since the universe, living and inanimate, is made of matter, physics must necessarily underlie all the other sciences.

III. THE WORLD OF THE CHEMISTS

WHAT CHEMISTRY IS ABOUT

Chemistry is the scientific study of the preparation, composition and architecture of chemical compounds, and of the modes and mechanisms of their transformations or reactions. Natural (and other) processes can be classified as *physical*, in which no chemical reactions occur, for example water running down a hill, and *chemical* if changes occur in the chemical compounds involved. Common examples are the burning of fuel, whether in a biological cell, an internal combustion engine, or a lowly domestic grate. Biological changes at the molecular level in plants and animals generally consist of many chemical reactions, as do some geological changes in rocks and deposits. Chemistry therefore is rooted in physics and interpenetrates biology (biochemistry) and geology (geochemistry). Some of the main sub-divisions of chemistry are delineated in the Table. Chemists not only aim to discover new reactions by trial and error, but by seeking to understand chemical change aspire to design new compounds and reactions. New reactions can be used to produce useful physical *effects* in new ways—like light from the cold chemical candle (chemiluminescence) as the firefly does, and electricity from more efficient batteries and from fuel cells—or to produce new *synthetic products*. These can be faithful copies of compounds like penicillin which have been discovered first in nature, or completely new, invented, compounds like sulphonamide drugs.

This research activity, which is mainly centred in the Universities, is the basis of a large chemical industry, one of the major manufacturing industries. Other branches which deal with more restrictive topics or use combinations of the above for specific goals have names which are self-explanatory, for example:—analytical chemistry, colloid chemistry, pharmaceutical chemistry, chemistry of dyes, petroleum chemistry, polymer chemistry, environmental and medicinal chemistry.

ELEMENTS AND COMPOUNDS

Elements

The reader will find a description of the formation of chemical elements in Part I. They are listed alphabetically in the **Table of Elements** (with their chemical symbols) and in order of atomic number in the **Periodic Table**. Other details may be found in **Section L**. They vary widely in natural abundance terrestrially.

In the earth's crust the most abundant elements are oxygen (O), silicon (Si), aluminium (Al), and iron (Fe). Our familiarity with them varies too, not only because of the rarity of some (thulium, Tm, and radium, Ra) and the artificiality of a few (plutonium, Pu) but because we meet some only in combination with other elements and not in their elemental state, for example, fluorine (F) in fluorides. The most familiar non-metallic elements besides oxygen and nitrogen in their gaseous molecular states (O_2 and N_2) are probably carbon (C), as graphite (or diamond!) and sulphur (S). Among the metallic elements most people know aluminium (Al), tin (Sn) and lead (Pb) from the main groups of the Periodic Table, and the transition metals: iron (Fe), chromium (Cr), nickel (Ni) as well as copper (Cu) and the precious metals silver (Ag), gold (Au) and platinum (Pt). Increasingly familiar because of their use in semi-conductors are the metalloids silicon (Si) and germanium (Ge).

Compounds

Most terrestrial matter as we know it can be classified in terms of the chemical compounds it contains, *i.e.*, is a mixture of compounds. Each compound consists of chemical elements in combination, the relative amount of each being characteristic and definite (Law of Constant Composition). Compounds vary not only in the number of elements combined but also in their proportions: carbon dioxide has twice as much oxygen per carbon as carbon monoxide (*see* atoms and molecules).

The properties of a compound can be, and normally are, very different from the properties of the elements it contains, a fact not commonly recognised in the popular imagination, witness phrases like—"it's good for you, it's got iron in it". This does not mean that elemental metallic iron is present but rather that some seemingly beneficial compound of iron is present. The ambiguity is that although iron is essential to human life in the form of haemoglobin in the blood, it also can form highly poisonous compounds. Similarly arsenic (As), although notoriously poisonous as the element and in some of its compounds, was nevertheless contained in one of the first chemotherapeutic drugs ever produced, salvarsan. The point can be further illustrated with sodium chloride, a water-soluble white crystalline solid, which is a compound of the very reactive metal sodium (capable of reacting violently with water), and of chlorine (known as a poisonous green gas). Similarly diamond (a particular elemental form, or allotrope, of carbon) is one of the hardest known substances but may be combined with hydrogen (the highly inflammable gas which can combine with oxygen gas to give water), to give thousands of different derivatives which include benzene (a liquid), methane (a gas) and various hydrocarbon waxes and polishes.

ATOMS AND MOLECULES

Atoms vary in weight, structure and size from one element to the next, as discussed earlier. Molecules are made from whole numbers of atoms in combination. A particular molecule is characterised by the number of atoms of each of its constituent elements. It has a characteristic weight

MAIN DIVISIONS OF CHEMISTRY

	Elements, Compounds and reactions involved	*Examples*
Organic Chemistry	Carbon in combination mainly with H, O, N.	Natural products Carbohydrates Steroids Proteins
Inorganic Chemistry	All elements and compounds not covered in organic chemistry. Minerals and salts.	Inorganic polymers (*e.g.*, silicones) Transition metal complexes Organometallic compounds
Physical Chemistry	Mathematical and physical descriptions of organic and inorganic compounds and reactions.	Electrochemistry Chemical thermodynamics Molecular spectroscopy Photochemistry
Biochemistry	The chemistry of biological systems	Enzymes Biosynthesis.

called its *molecular weight* (the sum of the weights of the atoms in it), and a characteristic three dimensional structure (*see below*).

An aggregate of molecules of the same type is a chemical compound, so that the molecule is to a compound as the atom is to an element.

The Mole

It is frequently very useful to know when the amounts of two compounds are the same, not in terms of their masses but in terms of the number of molecules each contains, since chemical reactions occur at the molecular level and involve small relative numbers of molecules of the reacting species at each step. Avogadro first suggested that equal volumes of gases under identical conditions contained equal molecular numbers and it followed that if the weights of two substances were in the ratio of their relative molecular masses (molecular weights) then they too contained equal numbers of molecules. The approximate molecular weights of water (H_2O) and ethanol or ethylalcohol (C_2H_5OH) are 18 and 46 respectively and so 18 g of water for example contain the same number of molecules as 46 g of ethanol.

The amount of substance referred to in each case is called 1 mole. For any compound the weight of 1 mole is equal to the gramme molecular weight. Molecular weights (or relative molecular masses) are now referred to the carbon-12 atomic scale. The modern definition of the mole therefore is that it is the amount of substance which contains the same number of elementary particles as there are atoms in twelve grammes of carbon-12. This number, called Avogadro's number, is $6{\cdot}022\,169 \times 10^{23}$.

Molecular Structure and Isomers

Modern spectroscopic and diffraction methods have enabled the details of molecular structures to be accurately determined not only with respect to the distances between atoms (normally in the range 1–5 Å”, *i.e.*, 100–150 pm for adjacent atoms) and the angles which define the structure, but also with respect to the various internal motions (vibrations and rotations).

Sometimes two (or more) different compounds have the same molecular weight (and are called, therefore, *isomers*) but have different molecular structures in which the same atoms are arranged in different relative positions, and hence have different properties. If two isomeric structures are related as left and right hands are related, the isomers are stereoisomers of a particular class called enantiomers. An example is glucose. Even such subtle variation as this produces differences in properties which can be crucial in biological function or drug metabolism.

A familiar simple example of *structural* isomers are ethylalcohol (or ethanol) and dimethyl ether of formula C_2H_6O. They each can be represented by the structural formulae

$CH_3{-}CH_2{-}OH$ and

$$\begin{matrix} CH_3 \\ \quad\backslash \\ O \\ / \\ CH_3 \end{matrix}$$

in which the lines represent some of the *covalent chemical bonds* (*see below*). It is these interatomic forces which hold the atoms in specific spatial arrangements. Some examples are shown on **T25**.

CHEMICAL BONDING

The number of possible arrangements of a given set of atoms is limited since each type of atom (each element) is capable of forming only a limited number of bonds, equal to its *valency*. The valency varies from element to element; hydrogen has a valency of one (exceptionally two); oxygen, two; nitrogen, three; and carbon four (hence the molecular formulae H_2, H_2O, NH_3 and CH_4 for hydrogen, water, ammonia and methane respectively).

In some compounds two atoms may be joined by a *multiple bond* so that the valency number may be reached. Examples are the double and triple bonds in ethylene (ethene) and acetylene (ethyne respectively:

$$CH_2 = CH_2 \text{ and } CH \equiv CH$$

The modern theory of chemical bonding is electronic. Bonds are formed:

(i) by the sharing of electrons in pairs between two bonded atoms (*covalent* bonding); or

(ii) by the transfer of an electron from one atom to another to form oppositely charged ions (*ionic* bonding).

The ionic situation is electrically *polar* whereas pure covalent bonds have no polarity. If, however, the shared electrons are not shared equally between the bound atoms some effective electron transfer occurs and the bond has some polar character. Covalent bonds between *dissimilar* atoms are generally polar. If one of the two atoms provides *both* the shared electrons, the polarity is particularly high and the bond is called *dative covalent*.

VALENCIES OF THE ELEMENTS

Electronic Theory of Valency

These ideas of the chemical bond lead to a ready explanation of the valencies of the elements (which are periodic if the elements are arranged in order of atomic number) when combined with knowledge of the electronic structure of atoms.

In the original Bohr theory the electrons of atoms move in well defined orbits arranged in shells. The known elements use seven shells, and each element has its unique number of electrons equal to the atomic number, Z ranging from 1 in hydrogen to 103 in lawrencium. Each element also has its unique arrangement of its electrons in these shells. The build-up of electrons in the above sequence follows well-defined rules. The resulting electron configuration of the elements is an important starting point for a discussion of valency. The shells each have a limited capacity and the numbers of electrons that can be accommodated in the first four labelled 1, 2, 3, 4 (or sometimes K, L, M, N) are 2, 8, 18, 32 respectively. Each of these shells has sub-shells of which there are four main types designated s, p, d and f which can contain 2, 6, 10 and 14 electrons respectively. If all the orbits in a shell have electrons actually present in them the shell is filled or closed and this confers on the shell an unusual stability or inertness. Conversely, unfilled shells lead to activity and the electrons in the incompletely filled shells largely determine the chemical and physical properties of the element and are responsible for the combination of atoms to form molecules. These electrons are referred to as *valence electrons*. The inner shell, *i.e.*, the one nearest the nucleus, can accommodate only two electrons (the element helium has just that number) and the next two shells can hold eight each.

Electropositive Elements

Large atoms, *e.g.*, lead, radium, have many filled shells and, subject to special exceptions, the general rule is that the inner shells are the filled ones and the outer shell may be incomplete. Elements which have equal numbers of electrons in their outer shell resemble each other and come in the same Group of the Periodic Table. Thus the elements with complete electronic shells are chemically unreactive gases, *e.g.*, argon and neon (minor constituents of the atmosphere). Elements with just one electron in the outer shell are highly reactive metals, *e.g.*, sodium and potassium which lose this electron readily to give monopositive ions, *e.g.*, Na^+. These elements are called electropositive. Contrariwise elements with just one electron too few are electronegative and readily gain one electron either by sharing, or by capture (to form anions, *e.g.*, Cl^-).

More generally, at least for the light elements of Periods 2 and 3 of the Periodic Table, the valence of an element is given by the Group Number, *N*, *i.e.*, the number of valence electrons which must be lost by the electropositive metals, or by 8-*N*, the number of electrons which electronegative elements need to gain.

VALENCE ELECTRONS (N) AND VALENCY (V)

N = 1	2	3	4	5	6	7	8
V = 1	2	3	4	3	2	1	0
Hydrogen							Helium
Sodium	Magnesium	Aluminium	Carbon	Nitrogen	Oxygen	Fluorine	Neon
Potassium	Calcium	Gallium	Silicon	Phosphorus	Sulphur	Chlorine	Argon
			Germanium	Arsenic		Bromine	
			Tin			Iodine	
	Barium		Lead				

← Metals → ← → Non-metals:

Positive ions Covalent compounds Negative ions or covalent compounds

The covalence of an electronegative element is increased by one if it loses one electron to form a positive ion, and decreased by one if it gains an electron. Thus nitrogen with a covalence 3 can give either N^- which can form 4 covalent bonds (in the ammonium ion, NH_4^-) or the N^- ion with a covalency of 2 (*e.g.*, NH_2^-). Similarly oxygen can give H_3O^+, the hydroxonium ion (the acid principle in water), H_2O (water itself), and OH^- (the hydroxyl ion).

IONIC BONDS, SALTS AND ACIDS

These bonds are normally formed between electropositive elements (at the left of the Periodic Table, *e.g.*, sodium and potassium) and electronegative elements (at the right of the Periodic Table, *e.g.*, oxygen, fluorine, chlorine). The ionic charge may be determined from the valency: Na^+, Mg^{++}, Al^{+++}; $O^=$, Cl^-.

Ions may contain a number of atoms, as shown by many of the common anions: hydroxyl, OH^-; nitrate, NO_3^-; sulphate, SO_4^{2-}; carbonate $CO_3^=$. Ionic solids formed from a metal ion and one of these anions are called *salts* and are derived from the parent *acid* in which the anion is bound to a *hydrogen ion* (or ions): HNO_3, nitric acid; H_2SO_4, sulphuric acid. Sulphuric acid can form two series of salts, one called *normal* based upon the SO_4^{--} ion and a second (called acid salts since they contain a hydrogen) based upon the HSO_4^- ion. Phosphoric acid, H_3PO_4, has three series of salts. A substance which reacts with an acid to form a salt and water as the only products is called a *base.* An example is sodium hydroxide, NaOH (caustic soda).

The ionic forces are less directional in character than covalent bonds are, but in solids the ions are in regular fixed arrangements (*see* **Part II**). Each anion is surrounded by cations and is attracted to them by electrostatic Coulomb forces. These are of long range and so the anion is attracted not only to the closest cations. Additionally each cation is surrounded by anions so that the bonding is not localised. The whole solid therefore is like a giant molecule and is not easily broken down by melting. This contrasts with covalent compounds in which the forces between molecules are small, the main attractions being within the molecule.

The structures adopted depend upon the relative numbers of the anions and cations (which are determined by ionic charges) and by the relative ionic sizes, which have been deduced from X-ray diffraction measurements.

COVALENT BONDS

In the simple theory the shared electron pairs are localised between two atoms. Multiple bonds result when there are more pairs shared. The multiplicity (or *bond order*) is then integral. The theory may be extended by admitting that an electron pair may be shared between more than two atoms in *delocalised bonding* which can then give rise to fractional bond orders. The best example is benzene (and graphite) where nine pairs of electrons are shared between six carbon-carbon bonds giving a bond order of 1·5.

Theories of Valency

Modern theories of valency make use of the concepts of quantum mechanics (*see* **T17**) in which each of the well-defined electron orbits of the s, p, d and f electrons in the Bohr theory is replaced by the idea of the electron cloud with a spatial electron density and distribution. Each of these electron clouds (now called an orbital) has a definite shape depending upon the type of electrons. The orbitals of s electrons are of spherical shape with a density that falls off with the distance from the nucleus. The peak density occurs at the old Bohr radius. Electrons of the p type have orbitals with double lobes giving the figure of eight or dumbell shape. There are three such orbitals in every shell except the first and they are arranged mutually at right angles. Each one can contain two electrons giving a total of six. The d orbitals are five in number. Each again can contain two electrons giving a total of ten. Four of these d orbitals have shapes like four-leaf clovers, whereas the fifth has two lobes, rather like the p orbitals but with the addition of a torus or doughnut. The shapes of the f orbitals are even more complicated. It is the shape of these orbitals and their relative spatial arrangement which gives the covalent bond its directional character.

Molecular Orbital

The idea of electron sharing between two atoms becomes the notion of overlap of an orbital on one atom with an orbital on another to give a bonding *molecular orbital* which can contain the pair of shared electrons. The bond energy is a maximum when this overlap is optimum and this occurs when the atoms are in certain definite positions thus giving the molecule its own characteristic shape.

Molecular Shape

For elements from the second row of the Periodic Table the number of electrons in the valence shell can be eight arranged in four pairs of orbitals (one 2s and three 2p orbitals). These orbitals can be combined or *hybridised* to give the basic tetrahedral shape (*see* Fig. 1). Each of these can overlap with say an orbital of a hydrogen atom (the 1s) to give a bonding orbital which can accommodate two electrons. Alternatively each orbital can, if the atom has enough electrons, contain two non-bonding electrons called a *lone pair.* The basic molecular shapes of methane (CH_4), ammonia (NH_3), and water (H_2O) may then be rationalised as in Fig. 1.

The bond angle in methane is the tetrahedral angle (109° 28′). The angles in ammonia (107° 18′) and water (104° 30′) are smaller probably because the lone pair orbital is slightly more repulsive than the bonding orbital is. This closes down the angles between the bonds.

The lone pairs may be used to bind the hydrogen ions from acids to give tetrahedral NH_4^- and pyramidal H_3O^-. It is the lone pairs therefore which give ammonia and water their basicity. In the modern concept of acids and bases due to Lewis, a base is an electron donor and an acid becomes an electron acceptor. This definition of an acid includes the older idea of it as a hydrogen ion

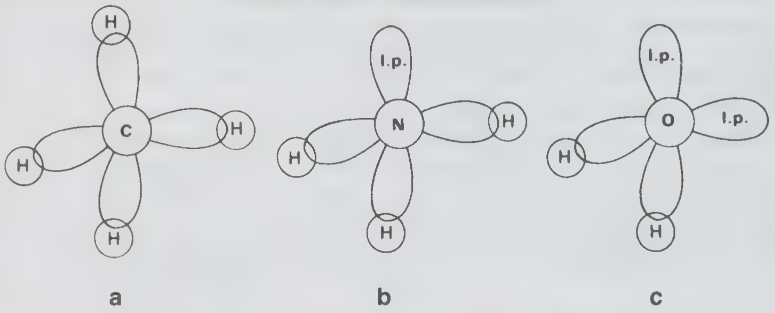

Fig. 1. The spatial arrangements of the atoms and orbitals in (a) methane (CH_4), (b) ammonia (NH_3) and (c) water (H_2O). The basic shape is tetrahedral and the hybridised orbitals are lone pair orbitals (l.p.) and bonding orbitals.

producer in that the hydrogen ion is an electron acceptor but it is more general—a Lewis acid need not be a protic acid.

Bond Lengths

Many covalent bond distances have been measured and each may be apportioned between the bound atoms to give a self-consistent set of covalent bond-radii for each element which can be used in predictions of molecular structures. These radii vary inversely with the bond order involved. Thus the carbon-carbon bond length varies from 154 pm (*i.e.*, 10^{12}m) for C−C to 135 pm for C=C.

Bond Energies

Bonds differ in their strength depending upon the atoms and the bond order. A double bond between two given atoms is stronger than a single bond but generally not as strong as two single bonds. Thus "unsaturated" compounds, which contain multiple bonds, will tend to form "saturated" compounds containing only single bonds since the energetics are favourable.

Functional Groups

Compounds may be further classified according to certain persistent groups of atoms which have a residual valency and can combine with other groups. Thus the methyl group (CH_3) related to methane (CH_4) by the removal of a hydrogen atom can combine with other atoms or groups of valency one: methyl chloride (chloromathane), CH_3Cl; methyl alcohol (methanol), CH_3OH; dimethyl ether, CH_3OCH_3. Common functional groups are shown in the table.

CHEMICAL ENERGETICS

Chemical reactions are accompanied by energy changes which can be utilised as heat (in fires) or mechanical work (in explosions or rockets), or to produce electric current in batteries. Chemical compounds can therefore be said to store energy and to possess "internal energy". The energy can be thought of as being stored in the chemical bonds. The energy change (at constant volume) in a reaction is then a result of changes (denoted ΔU) in the nett internal energy of the reactants and products by the law of the conservation of energy. If the conditions are those of constant pressure, the energy change is due to overall changes in a closely related properly called enthalpy (ΔH).

It was at one time thought that reactions would proceed only if energy was given out (*exo*thermic processes). Although this is now known to be

SOME CLASSES OF SIMPLE ORGANIC COMPOUNDS

Name	General Description and Formula	Examples
Alkanes (or paraffins)	"Saturated" hydrocarbons of the general formula C_nH_{2n+2} Contain single bonds only	methane (CH_4) butane (C_4H_{10})
Alkenes (olefins)	"Unsaturated" hydrocarbons of general formula C_nH_{2n} Contain double bonds	ethylene (C_2H_4) styrene ($C_6H_5.C_2H_3$)
Alkynes (acetylenes)	"Unsaturated" hydrocarbon of general formula C_nH_{2n-2} Contain triple bonds	acetylene (C_2H_2)
Alcohols	Contain the OH group, bound for example to an alkyl group $C_nH_{2n+1}OH$	methylalcohol (CH_3OH) ethylalcohol (C_2H_5OH)
Ketones	Contain the C=O group $C_nH_{2n+1}C{=}O$	acetone $(CH_3)_2CO$
Aldehydes	Contain the CHO group	fornaldehyde (HCHO) acetaldehyde (CH_3CHO)
Aromatic hydrocarbons	Ring compounds with reactions similiar to the proto type, benzene (C_6H_6)	napthalene ($C_{10}H_8$) anthracene ($C_{14}H_{10}$)
Phenyl compounds	Derivatives of the phenyl group, C_6H_5	phenol (C_6H_5OH) aniline ($C_6H_5NH_2$)
Heterocyclic compounds	Ring compounds containing mainly carbon atoms and one or more other atoms, *e.g.*, nitrogen	pyridine (C_5H_5N) thiophene (C_4H_4S)

true at the lowest temperature, in other cases a second consideration, the entropy term, needs to be considered, as the existence of *endo*thermic changes confirms. A new "energy" term defined to contain the entropy consideration and called the Gibbs Free Energy, G, may then be used. Natural or "spontaneous" processes are accompanied by a decrease in the nett value of G, and systems tend to assume whichever state has the lowest value of G.

Chemical Equilibrium

Certain chemical changes, like physical changes such as raising and lowering weights, or freezing and melting water, may be easily reversed. The forward and backward reactions which are proceeding continuously can then be made to balance out, given enough time, and the system is said to be in equilibrium.

Suppose that X and Y when mixed are partially converted to Z and an equilibrium mixture is obtained under certain defined conditions. The relative amounts $[X]$, $[Y]$, *etc.*, are then definite and governed by the equilibrium constant defined as

$$K = \frac{[Z]}{[X][Y]}$$

Putting it in another way, if we know K we can predict the relative amounts of products and reactants, *i.e.*, the extent to which the reaction proceeds. K in turn depends upon the change in Gibbs Free Energy for the reaction:

$$\Delta G = -RT \ln K$$

where R is the gas constant, and T the absolute temperature, and ln denotes the natural logarithm.

Chemical Thermodynamics

The efficiency of a reaction therefore can be predicted theoretically since values for ΔG can frequently be calculated from tabulated values of ΔH and ΔS. Such studies constitute *chemical thermodynamics*, the branch of thermodynamics applied to chemical reactions. It is an essential consideration in industrial processes.

Bond Enthalpies

The enthalpy (*q.v.*) of a molecule can be thought of as the sum of the enthalpies associated with each covalent bond, for each of which there is a characteristic value. Determination and tabulation of these bond energies helps in the prediction of enthalpy changes in new reactions involving covalent molecules. Similarly for ionic solids.

THE SPEED OF REACTIONS—CATALYSIS

A good analogy to illustrate the difference between chemical thermodynamics and kinetics is the downhill flow of water. The water will seek the lowest point where it has the lowest potential energy, and in an analogous way a reaction will try to proceed to the state with the lowest Gibbs Free Energy. However, the speed of both water flow and reaction will depend upon a large number of factors, particularly the available *pathway* (or reaction mechanism). Indeed water at the top of a mountain or in a domestic bath may not flow down at all if a suitable path is blocked say by a hillock (or bath plug). The unblocking may involve the expenditure of energy, for example to lift the water over the dam (or pull out the plug).

Activation Energy

In reactions this type of energy is called the *activation energy*. It can be supplied in a number of ways (*see below*) such as heating. Sometimes it is small and (thankfully) at other times it is large enough that thermodynamically feasible reactions do not occur at all quickly. Each of us is, in fact, *thermodynamically* unstable with respect to our combustion products, mainly CO_2 and H_2O, *i.e.*, we should burn (!), but fortunately we are *kinetically stable*.

Catalysts

A *catalyst* is a substance which will provide an alternative reaction pathway of low activation energy, *i.e.*, it can speed up a reaction, without itself being consumed in the process. The analogy for the water flow would be a tunnel through the hillock.

Catalysts are very important industrially, for example, in the manufacture of sulphuric acid (using platinised asbestos or vanadium pentoxide), in the Haber process for ammonia used for fertilisers (iron derivatives), and in the "cracking" of crude oil to give lighter oils (aluminium oxide). Natural catalysts are called *enzymes* (*q.v.*).

CLASSIFICATION OF REACTIONS

Chemical change can be brought about by a variety of techniques used separately or together:

mixing of single substances

heating single substances or mixtures

electrolysing solutions

exposure to light or radiation

addition of catalysts.

The changes can be classified according to the results produced:

Dissociation breakdown into simpler substances or ions

Addition—in which one type of molecule or ion is added to another

Polymerisation reaction of a substance (monomer) with itself to produce larger molecules of the same composition (polymer)

Substitution—in which one particular group in a molecule is replaced by another

Elimination—in which one particular group in a molecule is lost

Exchange—in which two groups are mutually substituted one by the other

Oxidation—removal of electrons (increase of oxidation number), *e.g.*, Fe^{++} ferrous ion is oxidised to ferric, Fe^{+++}

Reduction—the converse of oxidation

Classification by Molecular Mechanism

More significantly modern classifications are based upon the precise *molecular mechanism* employed. Examples are

Nucleophilic attack—where an electron-rich reagent attacks a position of low electron density in a molecule

Electrophilic attack—where an electron-depleted reagent—an electrophile (for example, a positive ion)—attacks a position of high electron density

Bimolecular reaction—one which involves two molecules unlike a monomolecular reaction which involves only one in each step

Precise descriptions can be built up: substitution, nucleophilic, bimolecular.

ELECTROLYTES, ELECTROLYSIS AND ELECTROCHEMICAL CELLS

Electrolytic Solutions

Ionic solids can dissolve in some solvents especially if each has a high dielectric constant to cut down the force of attraction between oppositely charged ions. The process can be assisted by solvation of the ions and also by the entropy changes which favour the less ordered state of affairs—the liquid rather than the ordered solid.

Electrolysis

The oppositely charged ions are capable of independent movement and the application of an electric potential from an external battery or source of direct current to electrodes in the solution will cause the ions to move. The positive ions (cations) will move to the negatively charged electrode (the cathode) and the negatively charged ions (anions) to the positively charged anode. At the electrodes chemical changes occur and ions may be converted to uncharged species and deposited: for example, sodium ions (Na^+) to sodium metal, Na. This process is referred to as electrolysis. Faraday discovered two laws of electrolysis: (i) the amount of any substance deposited (or dissolved) is proportional to the amount of electricity used; (ii) the relative amounts of substances deposited by the same quantity of electricity are in the ratio of their *equivalent weights.*

For any ion discharged below a certain value of the applied voltage the *discharge voltage* is small. In an electrolyte containing many different ionic species therefore, each ionic discharge will occur only as the appropriate potential is reached. For solutions of acids, hydrogen (formed from H^+ ions) is discharged at the cathode, and oxygen (formed from OH ions) at the anode. Electrolysis is important commercially for the refining of metals, electroplating, and in the production of many basic chemicals.

Electrochemical Cells

Ever since 1800 when Volta produced an electric battery consisting of alternate plates of silver and zinc separated by cloth impregnated with salt, the search for new batteries has been continuous. In each new battery a different chemical process is harnessed to produce electrical energy. The battery must not only be feasible according to the laws of thermodynamics, but must be practicable and cheap for widespread consumer use.

The voltages developed in any battery can be predicted from a knowledge of the two processes occurring: one at the cathode and the other at the anode. Voltages can be ascribed to each of these "half cells" according to the chemical reaction which occurs and the condition used, for example concentrations of the reactants (the so-called "standard electrode potentials"). The voltage of any combination of two half cells is the sum of the half-cell voltages. Furthermore each of these voltages is related to the change in the Gibbs Free Energy for its reaction and can, in theory, therefore be predicted thermodynamically.

CHEMISTRY IN MODERN LIFE

Chemistry plays a crucial role in modern life, not least in the third world, as well as in the more developed nations. In the UK chemistry has been studied, developed and put to practical use as well as anywhere in the world in modern times. It is no accident that the largest specialised scientific society in the UK is the Royal Society of Chemistry (RSC) and that its forerunner, The Chemical Society, lays claim to being the oldest in the world. The high quality of chemical science at the crucial level of basic research is indicated by the remarkable frequency with which the Nobel Prize in Chemistry has come to the UK The success is not confined to academic activity but, surely as a consequence, it extends to the economic life of the nation.

The UK Chemical Industry

The UK chemical industry is among the largest in the world and one of the most successful. It employs around 200,000 people in over 3,000 companies. In national statistics it is included in the manufacturing sector alongside other sectors which have a high chemical component such as petroleum and petroleum products. Its output covers a very wide range. Firstly there are the so called "basic chemicals", such as sulphuric acid, which are utilised in the manufacturing processes of other sectors.

Chemicals in Agriculture

In agriculture chemicals are not only important in the form of bulk products such as fertilizer, without which modern agriculture could not operate efficiently, but also for the 'finer' chemicals such as herbicides and insecticides. Manufactured synthetic polymers and plastics are omnipresent in modern life, for example in architecture and building as well as in many familiar household products and uses. The list here is long and includes moulded casings for televisions and other electronic and electrical products, kitchen utensils, all forms of coverings from paints and varnishes to fabrics. Then there are the "fine" chemicals: cosmetics and pharmaceuticals, ranging from vanity products to the birth control pill and life-saving synthetic drugs. Petroleum products from oil cover an extremely wide range. Petroleum is a most valuable "feed stock" for other products and in this use it is arguably more unique and precious than as a fuel or energy source.

IV. BIOLOGY—THE SCIENCE OF LIFE

WHAT BIOLOGY IS ABOUT

Biology embraces the study of all living things which exist on earth at the present time and also the recognisable remains of those that are extinct. Living things or organisms range from the apparently simple micro-organisms such as viruses and bacteria to the largest animals and plants.

Living Processes

The enormous variation and complexity of living processes make the task of understanding and defining life a very difficult one. Every living organism undergoes continual physical and chemical changes which, in spite of their diversity, are referred to as the metabolism of the organism. Metabolism involves the processing of food materials, the production of waste products, and all the intermediate stages between these whereby energy and matter are provided for the operation, maintenance, and growth of the organism. These reactions are under very exact chemical or nervous control at every stage and can be slowed down or speeded up as the need arises. Thus the organism can react to changes in the environment in which it lives, adjusting its activities in relation to the external changes. Finally, organisms can reproduce either in an identical or very slightly modified form. In this process new individuals are produced and the species continues to survive.

Differences between offspring and parents can, under certain circumstances, act cumulatively over many generations and so form the basis of evolutionary change in which new species of organism are ultimately formed. Viruses occupy a middle ground between biology and chemistry, as do the more recently discovered transposons, which are organisms in the genetic sense of undergoing replication but are so simple that they are amenable to chemical analysis. However, since these are intimately dependent on cellular organisms, they are included in the study of biology rather than chemistry.

Molecular Biology

It has been evident for many years that the most fundamental aspects of these living processes occur in basic structural units known as cells. The study of living processes at the molecular and cell level has been given a tremendous impetus in recent years by the advent of new techniques which enable microscopic and submicroscopic parts of cells to be examined. Physicists, chemists, and mathematicians have found themselves working alongside biologists in this field and several of the very notable advances have been made by physical scientists.

Molecular biology is a term frequently used in describing this rapidly expanding and fascinating field of research. A guide to some of the key terms in this field can be found on **T46–8**.

EVOLUTION

Introduction.—The idea that species of living organisms could change over long periods of time was considered by some Greek writers and, much later, by the Frenchmen Buffon and Lamarck at the end of the 18th cent. Further, the work of the 18th cent. geologists such as James Hutton and William Smith provided a basis without which the major contribution of Darwin, the great 19th cent. naturalist, would have been impossible. Hutton showed that the earth's surface had undergone prolonged upheavals and volcanic eruptions with consequent changes in sea level. This implied that the earth was much older than had previously been supposed. Smith developed a method of dating the geological strata by means of the fossils found in them and demonstrated that widely different types of animals and plants existed at different periods of the earth's history. Later in this section (**T63–6**) a more detailed picture is presented of the geological record of evolution.

These discoveries conflicted with the Biblical account in the book of Genesis and, although various attempts were made to explain them away or discredit them, it became abundantly clear that through millions of years life has been continually changing, with new species constantly arising and many dying out.

The Evidence for Evolution

1. The Geological Record.–It has already been pointed out that successively younger rocks contain fossil remains of different and relatively more complex organisms. The spore-bearing plants preceded the gymnosperms and the angiosperms arose much later. Similarly in the vertebrate series the fish appeared before the amphibia which were followed by the reptiles and later by the air breathing, warm-blooded birds and mammals.

On a more restricted level the evolution of the horse has been worked out in great detail from the small *Eohippus* which was about a foot high and had four digits on the forefeet and three on the hind-feet to the large one-toed animal living today.

However, such complete series are rare and the geological record is very incomplete. There are a number of gaps, particularly between the major groups of organisms. No satisfactory fossil evidence is known of the ancestors of the angiosperms so perhaps they did not grow in conditions which favoured their preservation as fossils.

On the other hand, *Archæopteryx* provides an indisputable link between the reptiles and the birds. For more discussion of these topics, *see* **T64–6**.

Although we talk about the age of fishes, the age of reptiles and so on it must be emphasised that these are the periods during which particular groups were abundant or even dominant. Each group probably originated many millions of years before it became widespread. Further, some groups, such as the giant reptiles and the seed-ferns, died out completely whereas others, the fishes and true ferns for example, are still common today although many fishes and ferns that exist today are very different from those of the Devonian and Carboniferous periods. On the other hand some species, *e.g.* the maidenhair tree, have remained unaltered for many millions of years.

2. Geographical Distribution.—Nearly all the marsupials or pouched mammals are found in the Australian continent which was cut off from the mainland about 60 million years ago. All the fossil evidence indicates that at that time the eutherian or placental mammals did not yet exist. The marsupials are the only naturally occurring mammals in Australia but since the isolation of the continent the group has given rise to a large number of species very similar in appearance to those which evolved elsewhere in the world among the eutherian mammals. There are marsupials which look like wolves, dogs, cats and squirrels; yet they have no close biological relationships to these animals. Further, some marsupials such as the kangaroos have evolved which are unlike any other creatures in the rest of the world. Quite clearly the isolation of Australia so long ago has resulted in the evolution of these distinct types, just as Darwin found in the Galapagos islands where each has its own distinct flora and fauna which differ also from those of the S. American mainland.

3. Anatomy.—The comparative study of the development and mature structure of the mammalian body provides much evidence that all the species have evolved from a single ancestral stock.

Although the arm of an ape, the leg of a dog, the flipper of a whale and the wing of a a bat appear very different externally they are all built on the same skeletal plan. It would be difficult to explain such similarities unless they had all evolved from a common type. There is also evidence that the early development of an animal recapitulates its biological history to a certain extent. For example, the gill slits found in fish are formed during the early stages in the development of a mammal although later they disappear. Finally, apparently useless vestigial structures sometimes occur which would be inexplicable unless regarded in the light of an evolutionary history. In man a small appendix and vestiges of a third eyelid occur but these are functionless although in other animals such structures are well developed and functional, *e.g.*, the appendix in the rabbit.

4. Human Selection.—During his brief history on earth modern man has continually selected and bred animals and plants for his own use. We have only to look at the various breeds of dogs which have been developed from a single wild type to see that under certain circumstances great structural divergence can occur in a species even in a relatively short time. The advent of genetic engineering may represent a qualitatively new form of evolution: many can now bypass the slow process of natural selection for small beneficial alterations in a species by rapid laboratory screening for dramatic changes selected to his advantage.

The Darwinian Theory of Evolution.—Darwin amassed a great deal of information such as that outlined above which convinced him that evolution of life had taken place over millions of years. His was the first real attempt to collect all the evidence scientifically and no other satisfactory alternative explanation of all the facts he presented has been proposed. Perhaps even more important was his attempt to explain *how* evolution had actually occurred. He published his theory after many years of work in his book *The Origin of Species by Means of Natural Selection* in 1859. Some of his ideas have since been modified owing to our increased knowledge of genetics but they are so important that it is worth-while recounting his theory.

1. The Struggle for Existence.—It is clear that in nature there is a severe struggle for existence in all animals and plants. Over a period of time the number of individuals of a species in a given community does not vary greatly. This implies that the number of progeny which survive to become mature breeding individuals more or less replaces the number of mature ones that die. Generally speaking the reproductive output of a species is much greater than this. For example, a single large foxglove plant may produce half a million seeds each one of which is potentially capable of giving rise to a new individual. Obviously nearly all the progeny die before reaching maturity and the chance of any single one surviving is very remote.

2. Variation.—The individuals of any generation of human beings obviously differ from one another and such differences are found in other organisms. It is clear that they vary considerably in structure, colour, activity and so on. Darwin also pointed out that generally these variations were passed on from one generation to the next, for example, the children of tall parents tend to grow tall.

3. Survival of the Fittest.—If there is an intense struggle for existence in their natural environment among individuals of a species having different characteristics, those which are best "fitted" to a given set of conditions are most likely to survive to maturity. These will reproduce and the features which enabled them to survive will be passed on to their offspring. This process is liable to continue and a species will become better adapted to its environment.

4. Natural Selection.—Over a long period of time the environment of a given species is never stable but will change in various ways. As it does so the characters which best fit the individuals to the changed environment will be selected. If an environmental change affects only part of the range occupied by a species, the populations living in different parts may adapt and come to differ so much that they are no longer able to interbreed, with the result that the original species has now become two distinct species.

Darwin and Lamarck.—Darwin pictured evolution as a slow continuous process with natural selection operating on the small inheritable variations found between the individuals of a species which were undergoing intense competition. This neglects the important effect of the environment on the growth and structure of the individual. It is obvious that external conditions will affect the development of an organism, for example the effect of various soil conditions on the growth of a plant or the amount of food material available to an animal. Lamarck maintained that the characters acquired by an individual owing to the effect of its environment could be passed on to its offspring. Undoubtedly characters are acquired by the individual during its growth but in spite of many attempts to prove otherwise no experiments have been done which prove conclusively that these are inherited by the offspring. Thus Lamarck's theory that evolution has occurred by the inheritance of acquired characters is not widely acceptable today.

Neodarwinism and the "Selfish Gene"

Darwinism received something of a setback during the early years of modern genetics. There did not seem to be much in common between the large mutations studied by geneticists and the small continuous variations which Darwin thought were the basic material upon which selection acted. With time, it became evident that not all mutations are large in their effects and that much of the continuous variation which occurs does indeed have a genetic basis. Mathematicians showed that even small selective advantages would cause genes to spread throughout populations as the generations passed by. Further development of this idea has led to the 'selfish gene' model, in which the struggle for existence, variation and survival of the fittest operate at the level of genes rather than whole animals, which are relegated to the role of mere vehicles allowing the expression of genes and, thus, the struggle between them. Experiments and observations on natural populations showed that evolution—seen as progressive, adaptive genetic change —does indeed occur today. For example, the proportion of dark-coloured moths has greatly increased in many areas where smoke pollution occurs, as a result of predation by birds on the now more obvious light forms. Again, many pest insects have evolved genetic resistance to the insecticides used to attack them.

Increases in the available fossil information suggest that evolution occurs in fits and starts, with long periods of stability alternating with short periods of rapid change. This is called the punctuated equilibrium model, and the 'punctuations' may be associated with sudden changes in climatic conditions.

GENETICS

Mendelism

Genetics is the study of the mechanisms of the hereditary process. Modern genetics began with the experiments of Gregor Mendel, an Austrian monk in 1865. He studied the inheritance of different factors in peas by crossing different strains and counting the numbers of plants with different characters in the succeeding generations.

In one experiment Mendel crossed peas with round seeds with peas having wrinkled seeds. All of the offspring (known as the "first filial" or F1 generation) had round seeds. Mendel allowed these plants to pollinate themselves, and then measured the characteristics of their offspring (the F2 generation). There were 5,474 round-seeded plants and 1,850 wrinkled-seeded plants in the F2 generation, a ratio of very nearly three to one. The character of roundness can be described as being "dominant" over the "recessive" character of wrinkledness.

In order to explain his results Mendel suggested that the characters of roundness and wrinkledness were determined by particulate factors (now called *genes*), and that each plant possessed two genes for each feature. Suppose the gene for roundness is *A* and that for wrinkledness is *a*. Then the parental plants in Mendel's experiment will be represented by *AA* (round seeds) and *aa* (wrinkled seeds). The gametes (the ovules and the sperm nuclei of the pollen grains) will be *A* and *a* respectively. When these combine to form the F1 generation they will produce plants with the genetic constitution *Aa*. Both male and female gametes of the F1 generation are then of the two types *A* and *a*, and these can combine, on self-pollination, in four different ways:

F1	male gamete	female gamete	F2
Aa	*A*	*A*	*AA*
	A	*a*	*Aa*
	a	*A*	
	a	*a*	*aa*

The individuals of the F2 generation will thus have genetic constitutions of *AA*, *Aa* and *aa* in the approximate proportions 1 : 2 : 1. Since both *AA* and *Aa* individuals have round seeds, the ratio of round-seeded plants to wrinkled-seeded plants will be about three to one, which indeed it is.

Mendel's results were ignored for many years until their rediscovery at the start of the 20th century. Mendelian ratios were then found to govern inheritance in a large number of other cases, such as coat colour in rabbits and cattle, and white eyes and other characteristics in the fruit fly *Drosophila*. In other cases characteristics are governed by more than one set of genes so the simple mathematical relationships are obscured. This occurs in quantitative features, such as yield in crop plants and weight in animals.

Application of modern statistical methods to Mendel's results suggest that they were subjected to certain 'massaging'—they are in fact simply too good to be true. However, many repeats of his experiments have shown that his conclusions are indeed statistically valid.

Early Chromosome Theory

The chromosomes are dark-staining filaments which, as we shall see later, can be observed in the nucleus at cell division. Their behaviour was described in the nineteenth century, but it was not clear what their function was. After the rediscovery of Mendel's work, Sutton suggested that the genes are carried on chromosomes, since the observed behaviour of the chromosomes corresponded very well with the theoretical behaviour of Mendel's factors.

Further evidence for the chromosome theory of inheritance came from study of the phenomenon known as sex-linkage, in which the expression of a gene depends upon the sex of the individual in which it is found. Haemophilia in man, for example, is a hereditary disease which is normally found only in males, although it is clear that females can act as carriers (Queen Victoria was one, since one of her sons, three of her grandsons and seven of her greatgrandsons were haemophiliacs).

Cytological study shows that there is one pair of chromosomes which differ in the two sexes. In the female (in man and most animals) the two chromosomes of this pair are similar and are known as the X chromosomes. In the male one of these is replaced by a much smaller Y chromosome. Hence recessive genes which are found on only one X chromosome are expressed in the male, since there is no other dominant gene present. A female haemophiliac would have haemophilia genes on both X chromosomes; this could only arise from a carrier mother and a haemophiliac father, a very rare occurrence.

The Composition of Chromosomes

In recent years it has become clear that chromosomes are composed largely of the DNA molecules of the cell nucleus (*q.v.*), to be discussed later. And since it has become evident that genes are DNA molecules, we now have a firm chemical basis for the assumption that genes are carried on chromosomes. Genetics has thus to some extent become a branch of molecular biology.

Mutations

Sometimes a DNA molecule may not replicate itself exactly during the process of cell division. When this happens the gene which it constitutes has changed its character so as to produce a difference effect when expressed in the individual organism. Such a change is known as a gene mutation. It seems likely, for example, that Queen Victoria's haemophilia gene arose as a mutation in herself or in her mother. Mutations, as we shall see, are of vital importance in providing the genetic variation upon which evolutionary selection can act.

The frequency with which mutations occur is increased by certain chemicals and by ionising radiation. Hence the need for caution in exposing the body to X-rays and to radioactive materials, and the concern over the possible genetic effects of radioactive waste from power stations and from military testing programmes.

THE CELL

Cells were first seen in 1665 by Robert Hooke when he looked at a piece of cork under his primitive microscope. It was not until 1839, however, that Schlieden and Schwann produced the cell doctrine which visualised the cell as both the structural and functional unit of living organisation. Viruses constitute a difficulty since in many ways they are intermediate between living and dead matter. They are absolutely dependent on cells of other organisms for their continued existence. Outside living cells they are inert molecules which may take a crystalline form. Inside a host cell, however, they become disease-producing parasites which multiply and show many of the other properties of living organisms. They are minute and lack the complex organisation usually associated with cells. Notwithstanding their somewhat ambiguous position, the viruses are often treated as though they were single cells or parts of cells and their extreme simplicity has made them ideal material for many types of research at this level.

Structure and Function of Cells

Though the constituent cells of a multicellular organism are usually specialised to perform particular functions, they have a great many features in common. The cell is often said to be made up of a substance called protoplasm, a term for the fundamental material of life which dates from the 19th cent. Protoplasm has two main constituents, the cytoplasm and the nucleus, and is bounded on the outside by a cell or plasma membrane. Plant cells generally have an additional wall composed primarily of cellulose and used for support. The nucleus is the controlling centre of the cell and has rather limited metabolic capabilities. The cytoplasm contains various organelles which operate to produce energy and new cell structure during the normal metabolism of the cell.

Cells take up the raw materials for metabolism through the cell membrane from extracellular fluid which surrounds them. The nutrients include carbohydrates, fats, proteins, minerals, vitamins, and water. Fats and carbohydrates are important principally as sources of energy, though both types of compound are found in permanent cell structure. Proteins are complex substances of high molecular weight which contain nitrogen in addition to the carbon, hydrogen, and oxygen found in the other compounds. They are of fundamental importance in the structure and function of the cell and are built up of a number of simple nitrogen-containing organic molecules called amino acids. There are twenty amino acids occurring commonly in nature so that the number of possible combinations in large protein molecules is quite clearly enormous. A group of proteins whose significance is well established are the enzymes which are the catalysts of chemical reactions in living cells. Each enzyme will control and speed up a specific reaction even though it is present in very small amounts and is usually unchanged at the end of the process. A large number of inorganic mineral salts are essential for cells to function normally. Some, such as sodium, potassium, and calcium salts, are needed in considerable quantity; others are required only in trace amounts and these include iron, copper, and manganese. The trace elements are usually important constituents of enzyme systems. Vitamins are also necessary in very small amounts and many act as 'co-enzymes', *i.e.* molecules which must bind to an enzyme before the enzyme is able to catalyse its specific reaction.

I. CYTOPLASM

For a long time cytoplasm was thought to be a homogeneous and structureless substrate in which enzymes occurred as part of a general colloidal system. With the refinement of techniques such as electron microscopy and ultracentrifugation, more and more identifiable components have been found within the cytoplasm. It now seems certain that the material other than these recognisable particles is not a structureless matrix but a highly organised and variable complex, organised around a network of protein filaments called the cytoskeleton, which is responsible for maintaining the internal distribution of organelles and also for cell movements, as in amoebae.

Mitochondria and Oxidation

Mitochondria vary in shape from cylindrical rods to spheres and in size from 0·2 to 3·0 μm. When seen in the living cell they are in constant motion. The whole structure is enclosed within a thin double membrane, the inner layer of which is thrown into folds extending across the central cavity of the mitochondrion and dividing it into small chambers. The function of mitochondria is to provide energy for the reactions of the rest of the cell. Almost the whole machinery for the oxidation of foodstuffs is to be found in the mitochondria. Slight damage to the mitochondrion will render it unable to carry out a complete cycle of oxidative processes. Destruction of parts of the double membrane system prevents the production of energy-rich phosphate bonds in adenosine triphosphate (ATP) in which energy is stored and transported about the cell.

Chloroplasts

Chloroplasts are particles found in cells in the green parts of plants, in fact they contain the green pigment called chlorophyll. They are involved in the process known as photosynthesis in which energy absorbed from light is used to synthesise carbohydrates from carbon dioxide and water, oxygen being formed as a byproduct.

Chloroplasts are disc-shaped or flat ellipsoids from 2 to 20 μm across, possessing a complex structure which in many ways is reminiscent of that found in mitochondria. A typical double membrane surrounds the structure and the inside is made up very largely of a stack of discs consisting of paired membranes connected at their ends to form closed systems. This seems to be a further development of the type of lamellated structure seen dividing the central cavity of a mitochondrion. The chlorophylls and other pigments, such as the orange yellow carotenoids, seem to be arranged in layers a single molecule thick in the chloroplast discs so that they are maximally exposed to light.

Photosynthesis

Photosynthesis is probably the most important of all biological reactions, and can be regarded as the basis of all higher life, and is responsible for producing the oxygen required for efficient metabolism. The whole animal population of the world, including man, is dependent on plants for food since even the meat-eating carnivores prey upon herbivores.

Although scientists continue to make efforts to produce adequate food materials from simple compounds, there is still no better machinery known for doing this than the plant cell. Man is dependent on photosynthesis for his supplies of food and also for much of his fuel, since much of the combustible material removed from the earth is of plant origin.

Ribosomes

Ribosomes, which are tiny granules composed of protein and RNA, are found in the cytoplasm, both free and attached to the surface of a system of membrane tubules called the endoplasmic reticulum, which permeates most of the cell. Ribosomes are responsible for the synthesis of proteins, which are bound to the endoplasmic reticulum and inject their proteins into the system of tubules as they are synthesised. The proteins can then be folded into the correct three-dimensional structure, modified by addition of sugar units, and transported to other parts of the cell. Some proteins accumulate in a special part of the endoplasmic reticulum, the Golgi apparatus, which lacks attached ribosomes and from which small vesicles bud off and later fuse with the plasma membrane to release their contents to the outside of the cell.

Nucleic Acids

The term nucleic acid covers a class of substances, usually of great complexity, built up from smaller units called nucleotides. Each nucleotide consists of a base, united to a sugar, in turn united to phosphoric acid. Nucleotides are joined together in a linear fashion by means of the phosphoric acid residues to form a chain from which the bases project at right angles into the centre of the double helix formed by two DNA molecules. Two types of sugar are found in naturally occurring nucleic acids and these are the ribose of RNA and the deoxyribose of deoxyribonucleic acids (DNA). We shall return to the latter when the nucleus is considered. Four nitrogen-containing bases occur in nucleic acids and in RNA—adenine, cytosine, guanine, and uracil. In DNA the uracil is replaced by thymine.

Protein Synthesis

RNA is predominantly manufactured in the nucleus and subsequently moves out into the cytoplasm. There are three major types of RNA, and all are involved in synthesising proteins. Ribosomal RNA, or rRNA, combines with a number of proteins to form the ribosomes, which act as the assembly line for proteins. Messenger RNA, or mRNA, carries a copy of the structural information encoded by a particular gene and, once in the cytoplasm, associates temporarily with ribosomes to have this information 'translated' into the structure of the protein. Transfer RNA, or tRNA, has a characteristic 'clover-leaf' structure, and picks up amino acids from the cytoplasm and carries them to the ribosome for addition to a growing protein chain. The information in genes and hence in the mRNA molecule is encoded as sequences of three of the nucleotide bases; each such *codon* tells the ribosome to add a particular amino acid to the protein it is making. Thus, as the ribosomes slide along the mRNA molecule, it stops at each codon, waits for the correct tRNA to arrive with the required amino acid, transfers the amino acid from the tRNA molecule to the growing protein, releases the used tRNA, and moves along to the next codon. mRNA molecules contain a number of special 'signal sequences' to tell the ribosome where to start and stop reading its instructions.

Nucleic acids are composed of four different nucleotide bases, while proteins are made using 20 different amino acids; mRNA molecules also need at least one codon as a 'start here' sign and another as a 'stop' sign. Clearly, a code of one base per amino acid would only be able to make proteins with four amino acids; a code of two bases per amino acid would be able to encode 16 amino acids, which is still insufficient. A code using three bases per amino acid can encode 64 amino acids, which is far more than enough, but is nonetheless the minimum that can be used. The genetic code is thus 'redundant', and most amino acids can be specified by more than one codon. Examination of the genetic code showed that redundancy is organised in such a way as to minimise the effects of changes in DNA nucleotides (mutation): thus, the amino acid valine has four codons, GUA, GUU, GUC and GUG, and changes in the last base will have no effect on the protein synthesised. Changes in the first position also have relatively minor effects, because all codons with U in the second position code for amino acids with only slightly different physical and chemical properties. Thus, evolution has taken great care to develop and maintain an optimal system for its own operating.

Cell Membrane

Though the cell membrane plays a most vital part in regulating what can enter and leave the cell, it remains rather poorly understood. It consists of two layers of lipid molecules with protein and other large molecules embedded within it. These protein molecules have many functions, including attachment of cells to each other, signalling the occurrence of extracellular events to the inside of the cell, and transport of water and other molecules into and out of cells. The first of these depends on the proteins and other molecules of different cells recognising each other and having the ability to join together; other adhesion molecules fix cells to various surfaces. Changes in cell recognition proteins are thought to be important in the spread of cancer cells through the body. Signalling functions involve proteins that pass right through the cell membrane and have, on the part exposed outside the cell, the ability to bind specific chemical compounds, such as hormones and neurotransmitters. When this occurs, the physical structure of the transmembrane protein changes, and this change is recognised by other proteins attached to the inner surface of the membrane.

This then induces an alteration in catalytic activity, for example increasing the production of cyclic adenosine mononucleotide (cAMP), which then diffuses to other parts of the cell to initiate changes in the activity of the cell. Such changes include increases in membrane permeability for sodium or potassium (as in nerve cells), increases in corticosteroid synthesis (as in adrenal cells) *etc*.

Second Messengers

The intermediate molecules such as cAMP in the example above are termed 'second messengers'. Transport of many substances, particularly metal ions (sodium, potassium, calcium) and sugars is mediated by membrane proteins which form pores through the membrane. These pores are of different sizes and chemical properties, which allows each pore type to be specific for a given chemical compound; this allows cells to regulate the composition of their contents very precisely. In many cases, regulation is by processes more complex than simple diffusion through a pore that can open and close; some pore proteins can actively pump ions across membranes, to give higher or lower concentrations inside the cell than outside. Such processes can be monitored by impaling cells with microscopic glass electrodes and measuring the voltages across their membranes; manipulation of the external conditions (*e.g.* removing calcium ions and adding substances known to open or close particular types of pore) can be used to determine which pores are active in a given type of cell and see how pore activity changes during biochemical and physiological processes such as conduction of nerve impulses.

II. NUCLEUS

The main regions of the nucleus are the surrounding nuclear membrane, a mass of material known as chromatin, and a small sphere called the nucleolus. The nuclear membrane is a double structure very much like the membranes of the cell surface and endoplasmic reticulum. Suggestions have been made that these membranes are continuous at some regions within the cell. The status of chromatin was in doubt for many years. Light microscope studies reveal very little structure in the nucleus until the time when the cell is preparing for, and undergoing, division or mitosis. At this time a number of discrete double strands, the chromosomes, are revealed by virtue of their chromatin content—the material stains heavily with basic dyes.

The nucleolus is a specialised region containing copies of the genes encoding ribosomal RNA, and are sites of intensive production of the latter. Thus, cells engaged in high levels of protein synthesis have a more developed nucleolar apparatus.

Mitosis

During division of body cells (mitosis) the chromosomes behave in regular and recognisable sequence. In the first stage called *prophase* they appear and at the same time the nuclear membrane breaks down. Next, in *metaphase*, the chromosomes become arranged across the equator of a spindle-shaped collection of fibrils which appears in the area formerly outlined by the nucleus. Then follows *anaphase* in which the two threads of each chromosome, the chromatids, move to opposite poles of the spindle. Finally in the last stage, *telophase*, nuclear membranes are formed round the two separate collections of chromosome material and the cytoplasm itself divides into two.

Thus two cells are formed each containing the same number of chromosomes as the parent and the cells enter a period of rest, or interphase, between divisions. During interphase the chromatin material disappears as the DNA spreads through the nucleus, the high level of organisation observed during cell division no longer being needed.

Meiosis

Division of germ cells (oocytes, sperm cells) is more complex, and occurs by the process of meiosis. This will not be described in detail here, but the essential point is that the parent cell has two sets of chromosomes, one inherited from the mother and one from the father. During meiosis, these are cut and rejoined to each other to produce 'mosaic' chromosomes, and one set is distributed to each of the two daughter cells. A new organism is formed when a sperm cell delivers its one set of chromosomes to complement the one set present in an egg cell to produce a new cell with two sets, from which the new organism develops.

Genes

These are the elements which contain all hereditary information and the medium whereby hereditary features are transmitted from one cell to the next, either in the same organism or from parents to offspring via the fertilised egg. Experiments indicated that the same genes always occupy the same position on chromosomes and this really demands a structural continuity through the life of the cell.

Thus, the DNA which is loosely packed during interphase, is 'condensed' into chromosomes for cell division by attachment of the necessary proteins; after division, the chromosomes are decondensed to allow the DNA to return to its normal function of specifying the metabolic activity of the cell.

One of the most fundamental problems in biology since the discovery of inheritance by means of genes has been the chemical nature of the genes and how genes are passed from generation to generation in such a way as to explain Mendelian inheritance. Genes have been shown to consist, at the chemical level, of DNA, and the structure of the DNA molecule was established by Watson and Crick.

DNA molecules are usually double-stranded, *i.e.* composed of two linear molecules arranged side by side. This is the explanation for a number of studies which showed that the proportions of the four nucleotide bases in DNA molecules from most sources follow a certain ratio, which results from pairing of A bases in one strand with T bases in the other and vice versa, and C bases in one strand pairing with G bases in the other and, again, vice versa.

The contribution of Watson and Crick, along with their under-known colleague Rosalind Franklin, to show that two linear DNA molecules joined together to form a double helix (*see below*) illustrates the complementary nature of the DNA molecule; the A-T and G-C pairs have different 'lock-and-key' structures which are responsible for the specificity of base pairing.

Molecular Theory of Genetics

The importance of these discoveries is that they provided the structural basis for our understanding of the mechanisms by which a long molecule, about 1 m of DNA in every human cell, can carry out its functions of transcription, replication and repair. These are all copying operations, involving the transmission of genetic information: organisms are the expression of information and DNA is the store of that information.

The information is copied to make RNA (transcription, for making proteins and thus bodies), to make DNA (replication, to make offspring), and to correct errors in one of the two strands (repair, to protect against mutation).

This molecular theory of genetics soon received extensive support, much of it in the form of complex and often subtle laboratory investigations. More dramatic support was provided by Khorana and his group when they started from simple chemicals bought in bottles and used a limited number of enzymes to assemble a bacterial tRNA gene; the artificial gene was found able to carry out many of the functions of the natural gene. Similar studies have resulted in the construction and manipulation of synthetic genes encoding a number of other molecules, particularly hormones. Building on these foundations, molecular genetics has now made vast advances.

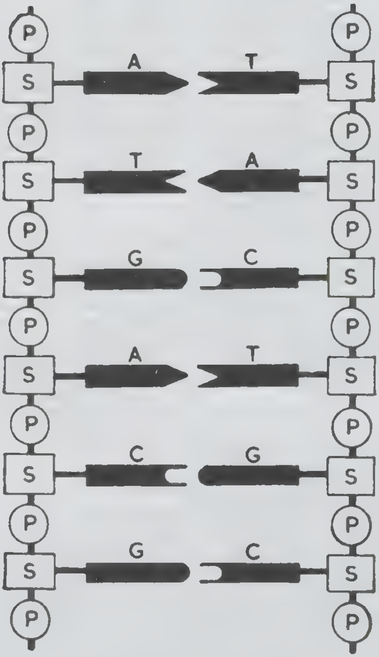

FIG. 1. A portion of a DNA molecule showing how it is made up of two strands of nucleotides. Each nucleotide consists of a base, which may be Adenine (A), Thymine (T), Guanine (G), or Cytosine (C), united to the Pentose Sugar, Deoxyribose (S), in turn joined to Phosphoric Acid (P). The nucleotides are linked through the phosphoric acid groups. The two strands are held together by hydrogen bonds between bases, adenine linking only with thymine, and guanine only with cytosine. They are twisted round each other so that the molecule is in the form of a double helix.

Note: Readers may wish to refer to the glossary of terms on **T46–8** which may provide help for those new to this important area of modern biology.

MULTICELLULAR ORGANISATION

It is axiomatic, if evolutionary theory is accepted, that in the course of very long periods of time there has been a general change in multicellular organisation from the simple aggregation of cells with little individual differentiation, to the highly specialised and differentiated cells and tissues seen in complex animals and plants.

Furthermore the complex organisation must be built up in the lifetime of each animal or plant from the single-celled stage of the fertilised egg. The essential problems in development are: (1) how is the smooth succession of shape changes produced during cell division so that an appropriate and recognisable end product is reached?; (2) how do the cells *differentiate* during this temporal sequence so that those which form part of the eye, say, are different from those of liver?

Differences in Development

There are some important differences in the method of development in animals and plants. In animals there tends to be a relatively short period during which the basic structure is produced and after which growth, repair, and replacement may cause adjustment rather than major change. In higher plants, on the other hand, the apical regions of both roots and shoots remain in a permanently embryonic state and add material, which then differentiates, in a continuous process throughout the life of the plant. In spite of these differences—and in any case there are many exceptions—the two main problems in development are similar in both animals and plants.

Work on Animal Development

A great deal of work has been done on animal development since this takes place in a fairly stereotyped way during a short period of time. The fertilised egg of an animal divides in such a way as to form a hollow ball of cells, the blastula, which folds in on itself to produce a two-layered sac, the gastrula. A third layer, the mesoderm, is now added between the two layers, known as ectoderm on the outside, and endoderm on the inside. At this stage much of the animal's basic structure is established. Many aspects of this orderly sequence can be explained in terms of specific adhesive properties of cells, so that a cell will stick to others of the same type but not to unrelated types. Other mechanical properties such as elasticity, particularly in surface layers, are important in maintaining shape and producing appropriate changes during processes when one layer is folded in on another. Why cells should have the different physical properties necessary to produce an integrated whole embryo is not known, but certainly it cannot be thought that every cell has an absolutely fixed constitution and therefore a predetermined role in development. Large parts of developing embryos can be removed in early stages and their places taken by remaining cells so that intact organisms are still produced.

Formation of Specialised Tissues

This is essentially a problem in the regulation of gene activity since each cell division generally produces daughter cells which are genetically identical. It seems likely therefore that instructions are carried on the chromosomes to cope with all requirements of the organism, but that in specialised cells only a small fraction of this full potential is realised. For a long time embryologists have known that egg cytoplasm shows regional differences which make identical nuclei behave differently, and it is thought that regional cytoplasm can in some way control gene activity. Techniques for the transplantation of nuclei in developing frog embryos have been perfected and it has been possible to put a nucleus from an intestinal cell of a tadpole into an enucleate egg. The egg will go on to develop normally even though its nucleus came from a fully specialised cell derived from endoderm. The embryo will form blood and muscle from the mesodermal layer and all the other components of an organism, under the influence of a nucleus which normally would have produced none of these things. One can conclude that all the genes are present, even in the nuclei of specialised cells, but that they have to be placed in a suitable cytoplasmic environment in order to be activated. Similar nuclear transplantation experiments indicate that genes can be "turned off" as well as "turned on" by an appropriate cytoplasmic environment, even though the nuclei come from cells which are so specialised as to stop dividing. Chemical signals secreted by cells in particular parts of the embryo are known to play a major role in directing the differentiation of nearby cells to form a variety of body structures. The cells receiving these signals respond differently to the local concentrations of these chemicals.

A study of cell differentiation and the development of multicellular organisation leads us to the view that, important though the nucleus and its genes are in controlling cell activity, an integrated organism is the result of complex interactions between its constituent cells and between the cytoplasm of those cells and their nuclei.

THE CLASSIFICATION OF ORGANISMS

Ray and Linnaeus It was clear to the biologists of the 17th cent. that animals and plants could be fitted into different groups or species. John Ray, a leading biologist of the day, defined a species as a group of individuals capable of interbreeding within the group. This criterion, with its corollary that a species is reproductively isolated from organisms outside the group, has survived more or less unchanged to the present day. The early workers also saw that some species were very similar to one another while others were obviously dissimilar. Systems of classification based on the similarities and differences were drawn up so that all organisms could be fitted into an orderly scheme and species could be given names in accordance with the scheme. The most famous collector and classifier was the Swede, Linnaeus. A very large number of animals and plants are known by the names given to them by Linnaeus.

Systematics, as this type of study is called, acquired a new significance after Darwin and the theory of evolution. The most satisfactory classification became one which reflected the evolution of the organisms classified, a so-called natural classification. It is not always easy to produce because ancestral types tend to become extinct and the problem then becomes one of reconstructing a whole branching system when only the ends of the branches are known. A great deal of the work on systematics has, of necessity, to be done on museum specimens which may be fossils or material preserved in some way by the collectors. The biological criterion of reproductive isolation cannot be used to define a species when the only available representatives are in a preserved state. In this case the scientist must resort to an assessment of structural differences in an attempt to decide whether two organisms are of different species. Other fossil evidence found at the same site as the fossil being classified is often important, in that it can provide evidence of biological and behavioural characteristics such as the type of food consumed and nest-building activity. In recent years computer techniques have been used to compare large numbers of structural differences between groups of animals or plants, as well as physiological and biochemical characteristics. All these techniques have led to the realisation that even the species cannot be regarded as a static point in an evolutionary pattern. Some species die out and others arise as the environment changes.

When the systematist shifts his attention to the higher levels of classification the problems are just as great as at the species level. Different species having features in common can be grouped together into genera, genera into families, families into orders, orders into classes, and classes into phyla. The dividing lines between different groups at all levels is always difficult and in the final analysis somewhat arbitrary since at these levels we do not have any biological criterion such as exists for the species. The evolutionary status of the larger groups is also poorly defined. Many are now recognised to be polyphyletic, which is to say that there are several main evolutionary lines running right through the group.

THE ANIMAL KINGDOM

The animal kingdom is divided into about 24 large groups or *phyla* though the number varies between different classifications. Ten of the more important *phyla* are listed below.

1. Protozoa.—Microscopic, unicellular forms of great variety. Some may have more than one nucleus and others form colonies. Many are able to swim by waving hair-like flagella or cilia. Others move by putting out extensions of the body or pseudopodia into which the rest of the body then flows. Protozoa are found in the sea, in fresh water and in the soil. Some are parasitic and cause important diseases in both animals and humans such as sleeping sickness and malaria.

2. Porifera.—Sponges. Very primitive, multicellular animals whose cells display considerable independence of one another. Largely marine. The body which may become branched and plant-like is supported by a framework of spicules and fibres. The bath sponge is the fibrous skeleton of certain species.

3. Coelenterates.—Hydra, jellyfish, sea anemones, corals. Simple animals which have a body only two cells thick surrounding a gut cavity with a single opening to the outside. Largely marine. Many are colonial. Coral reefs are formed from the calcareous skeletons of these animals.

4. Platyhelminths.—Flatworms, which are free living in water, and liver flukes and tapeworms, which are parasitic. A third, solid block of cells, the mesoderm, has been developed between the two layers of cells seen in the coelenterates. A simple gut may be developed and the reproductive system is complex especially in the parasitic forms.

5. Nematodes.—Roundworms. The body is smooth and pointed at each end. Some of the most numerous and widespread of all animals. Free living in all environments and parasitic in practically all groups of plants and animals. The same level of complexity as the Platyhelminths.

6. Annelids.—Segmented worms such as earthworms, marine worms and leeches. A system of spaces, the body cavity, is developed in the mesoderm so that movements of the main body of the animal and movements of the gut become more or less independent. Digestive, excretory, circulatory, nervous and reproductive systems are all well developed.

7. Arthropods.—A very large, diverse and important group of animals which includes crustaceans such as crabs, shrimps and water fleas; myriapods, such as centipedes and millepedes; insects; and arachnids, such as spiders and scorpions. The arthropods show many of the developments seen in annelids and in addition they possess a jointed, hard *exoskeleton*. Paired appendages grow out from the segments of the body and form antennae, mouth parts, walking legs, *etc*. The muscles within the skeleton are able to exert a fine control over the movement of the appendage. In order to grow these animals have to shed the exoskeleton periodically.

Around 80 per cent of all animal species alive today are arthropods. There are around 350,000 types of beatles alone!

8. Molluscs.—Mussels, clams, oysters, squids, octopods and snails. Complex body form but somewhat different from annelid-arthropod type. Unsegmented body protected by shell which is variously developed in different types. It forms two valves in mussels and oysters, a spiral structure in snails, is reduced and internal in squids and completely lost in octopods. There are over 70,000 known species of molluscs. The giant clams of the Pacific coral reefs are the largest in the world.

9. Echinoderms.—Starfish, brittle stars, sea cucumbers, sea urchins, and sea lilies. All marine and all radially symmetrical, usually with five radii. Completely unlike the other advanced, major groups. Circulatory, excretory and nervous systems differently developed. Locomotion and feeding by means of hundreds of tube feet projecting from under surface.

10. Chordates.—Sea squirts, Amphioxus, fish, amphibia, reptiles, birds and mammals. Segmented animals which at some stage in their life have gill slits leading from pharynx to the outside and a supporting notochord from which, in all chordates except sea squirts and Amphioxus, is developed a vertebral column or backbone.

Those animals with a backbone are commonly referred to as vertebrates, *all* those without as invertebrates. These are obviously names of convenience having no phylogenetic significance since they lump together totally unrelated phyla in one case and align these with a part of a single phylum in the other. The vertebrates have been investigated more completely than any other animals because of their direct structural and functional relationship with man himself. There are five well defined classes which are listed below.

The first vertebrates were the fish and from them came the amphibia. The amphibia gave rise to the reptiles and both birds and mammals evolved from different reptilian stock.

(a) Fish

Cold blooded, aquatic animals breathing by means of gills. Sharks, rays and dogfish belong to a group known as the elasmobranchs characterised by a skeleton made of cartilage. Bony fish, most of them in a group called the teleosts, include almost all the fresh water fish and the marine fish such as cod, plaice, herring, *etc*.

(b) Amphibia

Cold blooded, more or less terrestrial animals which have to return to water to breed. Five-fingered limbs are developed in place of the fins of fish. The egg hatches into a tadpole larva which is aquatic and breathes by gills. At metamorphosis the larva changes into the terrestrial adult which possesses lungs. Some amphibia such as the axolotl may become sexually mature as a larva and so never metamorphose into the adult. The class includes newts, salamanders, frogs *etc*.

(c) Reptiles

Cold blooded and terrestrial. These animals do not return to water to breed because they have an egg with a relatively impermeable shell containing the food and water requirements of the developing embryo. There is no larval stage.

Present day reptiles such as lizards, snakes and crocodiles are all that remains of a tremendous radiation of dinosaur-like creatures which occurred in the Mesozoic period.

(d) Birds

Warm blooded and adapted for aerial life. The characteristic feathers are both to insulate the body against heat loss and to provide the airfoil surfaces necessary for flight. The birds are an astonishingly uniform group and show less diversity of structure than much lower classification categories (*e.g.*, the teleosts) in other classes. The relationships of the 8,000 or more species of bird are difficult to establish because of this uniformity. It is clear that the flightless forms such as the ostrich are primitive and that the penguins are also in a separate category but the typical modern birds are classified in a large number of rather arbitrary orders. About half of all the known species are placed in one enormous order called the Passeriformes or perching birds.

(e) Mammals

Warm blooded animals which have been successful in a tremendous variety of habitats. Mammals are insulated from the environment by the characteristically hairy and waterproofed skin. They are, with two exceptions, viviparous which means that their young are born alive and in typical mammals at an advanced stage of development. In the marsupials of Australia the young are born at an early stage and transferred to a pouch where they develop further. The two exceptions referred to are primitive monotreme mammals known as the duck-billed platypus and spiny ant-eater and these animals lay eggs. The young of mammals are suckled by means of the milk-producing mammary glands. The mammals include aquatic whales and dolphins, hoofed ungulates, flesh eating carnivores, rodents and insectivores, the aerial bats, and the tree-climbing primates to which man himself belongs.

There are over 5,000 species of mammals on the planet today (and *c.* 2,000 of them are rodents).

Modern geneticists now put all the placental mammals into four great groups—*Afrotheria*, *Laurasiatheria*, *Xenarthra* and *Glires-Euarchonta*. The surprising bedfellows brought about by this new grouping may cause biologists to redraw traditioonal classifications.

THE PHYSIOLOGY OF ANIMALS

In multicellular animals cells are of various types, constituting distinct tissues and organs which perform special functions in the body. Although each cell has its own complex metabolism there must be coordination between cells forming special tissues and between the tissues which form the whole organism in order for the body to function efficiently. The study of these functional interrelationships at the tissue and organism level of organisation is the province of the physiologist.

1. Movement, Fibrils and Skeletons

(*a*) **Muscles.**—The prime movers in almost all animal movement are large protein molecules in the form of microscopic fibrillar threads. These fibrils convert the chemical energy stored in the high energy phosphate bonds of ATP into mechanical energy. In the long, thin cells forming the muscles of animals, it has been discovered that there are two sets of fibrils, one formed of a protein called myosin, the other of actin, arranged in a regular, interdigitating fashion. When the muscle contracts the fibrils slide past one another so that, although the fibrils themselves do not change in length, the muscle as a whole develops tension and shortens. Fine bridges extend from the myosin fibrils to attach on to the actin and it is here that the conversion of chemical to mechanical energy goes on.

(*b*) **Skeletons.**—In order for muscles to work effectively it is necessary for them to operate in some sort of skeletal system. Contraction but not relaxation is an active process; muscles are usually arranged in antagonistic pairs so that one muscle can extend the other. A skeleton also provides a system of levers so that the muscles can do work against the environment in an efficient manner. A simple type of skeleton found in fairly primitive animals is the hydrostatic system of coelenterates and worms. Here the animal can be thought of as a fluid-filled bag or tube which can change shape but whose volume remains constant. By contraction of circular muscles the tube will become long and thin and conversely the contraction of longitudinal muscles makes the tube short and fat. Examination of an earthworm will demonstrate how alternating waves of activity of this type passing from head to tail can move the animal over the ground. The earthworm shows an advance over the simplest systems because the hydrostatic tube is broken up into small units by the segmentation of the body. This makes local responses possible. The next advance to be seen is the development in animals such as arthropods and vertebrates of a firm skeleton to which muscles are directly attached. The skeleton can then be used to support the body and to engage the environment. It seems to matter little whether an endoskeleton (vertebrates) or exoskeleton (arthropods) is developed since in both cases a tremendous radiation of fins for swimming, legs for walking and wings for flying can be seen. However in other respects these two types of skeleton show significant differences. The exoskeleton for example offers more protection than the endoskeleton while apparently setting an upper size limit. All the really big animals have endoskeletons.

(*c*) **Cilia.** -Fibrillar systems are also seen in the hair-like cilia which project from the surface of some cells. Cilia are important in a number of ways. They are the organelles of movement in many protozoa, they are used to produce water currents past the bodies of some aquatic animals, and they are of great importance in moving fluid within the body of almost all animals. They beat in a regular fashion, the effective stroke being accomplished with the cilium held straight out from the surface and the recovery stroke with the cilium flexed at the base.

2. Feeding

All animals require complex organic substances, proteins, fats and carbohydrates, together with small amounts of salts and vitamins. These materials are obtained by eating the dead bodies of plants and other animals. They are taken into the alimentary canal and there broken down or digested by enzymes into simpler, soluble amino acids, sugars and fatty acids. These substances are absorbed and distributed to various parts of the body where they are used in cell metabolism (*q.v.*) or stored for future use.

Macrophagous Feeders. Many animals, called macrophagous feeders, take in relatively large masses of food. Some such as frogs and snakes swallow their food whole, but many break it up first. Arthropods have modified appendages arranged round the mouth for cutting, some molluscs have a rasp-like radula with which to scrape off particles, and many mammals break up their food with jaws and teeth. The teeth are usually well adapted to the type of food. Carnivores have large, sharp canines, premolars and molars with which to tear the flesh of the prey, fish-eating seals have small peg-like teeth to grip the fish and herbivorous ungulates have flat grinding teeth with which they break up hard plant material.

Microphagous Feeders. In contrast, microphagous feeders collect small particles of food material from the environment by continuous filtration. In bivalve molluscs and many marine worms water currents are produced by beating cilia. Food is trapped within the confined space through which the water flows by means of a plentiful supply of sticky mucus in the filtering region. Some crustacea use fine hairs to sieve off food material, often from water currents created by the swimming movements. The most startling of filter feeders is the whalebone whale. As the whale swims forward a stream of water flows in at the front of the mouth and out at the sides via sheets of whalebone which filter off the organisms on which the animal feeds. Though macrophagy seems to favour the attainment of larger size there are exceptions! Another type of particulate feeding is seen in those animals which eat deposits of detritus as do many worms. Finally some animals take in only soluble food materials. These fluid feeders include internal parasites like the tapeworm which absorb substances over the surface of the body, and insects such as the aphid with sucking mouth parts.

3. Respiration. Gills, Lungs and Tracheae

All living cells respire and remain alive only if supplied with oxygen. In a multicellular body, however, many cells are remote from the oxygen of the environment and the need arises for an efficient respiratory system by which oxygen can be taken up and carbon dioxide released. In addition a circulatory system is necessary to transport the oxygen to and from the respiring cells.

(a) Simple Gas Exchange Systems

Animals such as protozoa do not need special structure for gas exchange. Diffusion over the whole body surface ensures an adequate supply of oxygen. Much larger animals such as earthworms also find it possible to rely on diffusion alone, partly because their consumption of oxygen is fairly low, and partly because their bodies are permeable all over. For various reasons most animals restrict the permeability of the outer layers of the body and under these conditions special respiratory areas have to be developed.

(b) Gas Exchange in Water

Aquatic animals, except those such as whales breathing at the surface, have to obtain their oxygen from the supplies which are dissolved in the water. This presents several problems because water is a dense medium, there is not a lot of oxygen in solution, and its diffusion rate is low. For these reasons there is a surprising functional uniformity in gill systems and they are very different from lungs. Gills are fine, finger-like processes with a good blood supply which are held out in a water stream. The water current is brought very close to the gill filaments so that the length of diffusion pathway for oxygen is minimal.

There is a "counter current" flow of water and blood so that the water containing most oxygen comes into contact with the blood just leaving the gill. This ensures that most of the oxygen can be transferred from water to blood through the thin gill cells. The efficiency of "counter current" systems is well known to the engineer but they were invented by aquatic animals long before they were by man. These features can be seen in the gills of molluscs, crustacea and fish.

The pumping devices maintaining the water currents also operate economically. Flow is maintained in crustacea by appendages modified to form beating paddles, in many molluscs by ciliary movement, and in fish by the operation of a double pump in mouth and opercular cavities. In almost all cases there is a continuous current over the gills, the water coming in one way and going out another. Thus the animal avoids reversing the flow with the consequent waste of energy in accelerating and decelerating a large mass of water. Fish, for example, take water in at the mouth and force it out through the gill slits (sharks) or operculum (teleosts).

(c) Gas Exchange in Air

Air breathing animals do not encounter these problems since the medium is less dense, contains a great deal (21%) of oxygen and diffusion rates are high. Lungs are therefore in the form of sacs whose walls are well supplied with blood. The area of the walls may be increased by folding so that the lung becomes spongy and full of minute air spaces called alveoli where the gas exchange goes on. Only the main airways receive fresh air as the lung expands; oxygen is renewed in the alveoli by diffusion. Ventilation of the lung is accomplished by a tidal flow of air in and out of the same tubular opening known as the trachea. The actual ventilating mechanism varies in different animals. In the amphibia for example air is forced into the lungs when the floor of the mouth is raised with the mouth and nostrils shut. The lungs are emptied by elastic recoil and by lowering the floor of the mouth. Higher vertebrates use a costal pump which changes the volume of chest and lungs by movements of the ribs. This change in volume is further assisted in mammals by the diaphragm, a sheet of muscle which lies beneath the lungs and separates thorax and abdomen. In many animals sound producing organs are associated with the lungs and trachea. The larynx is a vocal organ in frogs, some lizards, and most notably mammals. In birds voice production takes place in the syrinx situated further down at the base of the trachea.

A completely different gas exchanging system is seen in insects. Branching tubes, known as tracheae, run throughout the body and carry oxygen directly to the cells without the intervention of a blood system. The tracheae communicate with the outside world via a series of holes called spiracles. Although the main tubes may be actively ventilated, diffusion in the system accounts for a large part of the movement of oxygen between the outside world and cells.

4. Circulation

In the larger animals a transport system is necessary to convey materials about the body and in many it is in the form of a blood system. Blood systems are of two types, closed and open.

(a) Open Systems

In an open circulatory system blood is pumped from the heart into a few major arteries but these very quickly give way to large tissue spaces or sinuses so that the tissues and organs of the body are directly bathed in blood. Blood flows slowly from the sinuses back to the heart. Both mollusc and arthropods possess an open system.

(b) Closed Systems

In a closed system blood is pumped round the body in a branching network of arteries and comes into contact with tissues and cells via very thin walled vessels called capillaries. Substances diffuse into and out of the blood through capillary walls. From capillaries, blood enters the veins and so returns to the heart. Blood flow in the tubes of a closed system is much more brisk and blood pressures tend to be higher than in an open system. In annelids the closed system is fairly simple with a vessel above the gut in which blood moves forward connecting to one below in which blood moves backwards. The blood is pumped by peristaltic contraction of the vessels and this system is the precursor of a localised pump. Simple hearts are in fact seen in some annelids.

In vertebrates a well defined heart is always present, situated ventrally at the level of the forelimbs. In fish there is a single auricle and ventricle and the latter pumps blood directly to the gills. From the gills the blood is collected into a dorsal aorta which then branches to serve the rest of the body. Associated with the development of lungs and loss of gills in the tetrapods, we see a progressive modification of this simple pattern. The most posterior gill vessel is taken over as the lung or pulmonary artery and slowly a completely separate circuit evolves. This involves the division of the single heart into right and left sides, the former pumping blood to the lungs and the latter to the body. In the birds and mammals where the division is complete the system can be seen to be functionally satisfactory. Blood flows along the following route: left auricle to left ventricle, to body, to right auricle, to right ventricle, to lungs, to left auricle, and so on. Thus blood charged with oxygen in the lungs returns to the heart before being pumped to the body.

(c) Function of the Blood

Most of the materials transported by the blood such as nutrients, waste materials and hormones are carried in solution in the plasma. The respiratory gases, oxygen and carbon dioxide, are present in greater quantity than would be possible if they were in simple solution. Carbon dioxide is carried in the form of bicarbonate and oxygen combines with blood pigment. The best known blood pigment is haemoglobin which is found in a variety of animals and gives the red colour to blood. When oxygen is present in high concentration, as it is in the lungs, combination occurs to give oxyhaemoglobin. If the concentration of oxygen is low, as it is in the tissues, dissociation occurs and oxygen is given off leaving reduced haemoglobin. Carbon monoxide will combine more readily than oxygen with haemoglobin so that in carbon monoxide poisoning the blood cannot transport oxygen. The haemoglobin of vertebrates is contained in high concentration in red blood corpuscles. The amount of haemoglobin and, hence, oxygen carried is greater than if the pigment is not in corpuscles. In mammals the oxygen carrying capacity of blood is thirty times that of a similar quantity of water. Other blood pigments are the blue haemocyanin found in crustacea and molluscs, and the violet haemerythrin found in some worms. Also present in the blood are various types of white corpuscle which are part of the defence mechanism of the body and ingest invading bacteria. Special blood proteins such as fibrinogen, causing clot formation, and antibodies effective against foreign substances occur in the plasma.

5. Excretion, Ionic Regulation and Kidney Tubules

As the chemical reactions included under the term metabolism proceed, so numerous waste products accumulate. The most important of these are compounds containing nitrogen, such as ammonia, urea and uric acid, arising from the use of protein as an energy source. In terrestrial animals they are removed from the blood by the kidney. The basic unit of a kidney is the tubule; in worms these tubules are not concentrated into a solid kidney but occur, a pair in every segment, right down the body. The kidney tubule begins with an end sac, corpuscle or funnel which is closely associated with the body cavity or the blood system. Fluid is filtered from the body cavity or blood into the corpuscle whence it passes to the tubule proper. During passage down the tubule, useful materials are reabsorbed through the tubule cells into the blood. Unwanted materials remain and pass to the outside world.

Although it is usual to think of kidney function being primarily one of nitrogenous excretion, it is quite common to find that in aquatic animals the kidneys are hardly used for this purpose. In these animals the tubules are primarily concerned in regulating the salt and water levels in the body, nitrogenous wastes being eliminated by diffusion through any permeable surface. In fresh water for example all animals have osmotic problems since the body fluids have a much greater osmotic pressure than the environment. Water tends to enter the body and salts tend to leave. Fresh water animals produce large quantities of very dilute urine, filtering off a lot of blood plasma into the tubules but reabsorbing all wanted materials including the invaluable salts. Fresh water crustacea, molluscs and fish all possess tubules of different morphology which show very similar functional properties.

Different environmental conditions impose different demands on the osmotic and ionic regulating machinery. In very dry conditions, such as in deserts, it is obviously of advantage to reabsorb as much water from the tubule as possible. All animals do this but it is interesting that only birds and mammals have discovered the secret of so concentrating the urine that its salt concentration is higher than that in the blood. This is done by means of a hairpin-like loop in the tubule called the Loop of Henle, another counter current device.

6. Co-ordinating Systems

Overall co-ordination of the animal's body, so that it functions as a whole and reacts appropriately to environmental changes, is largely the province of two systems, one chemical or hormonal, the other nervous. In one respect these are systems for homeostasis, that is for preserving the *status quo*, in spite of considerable environmental fluctuation. Paradoxically they can also initiate change as, for example, one can see in the daily repertoire of complicated behaviour patterns produced by almost any animal.

(a) Nervous Systems

(i) Sensory Information

Before appropriate reactions can be produced to any stimulus it is necessary to measure its intensity, position, duration and, most important, character. This is done by sense organs which are usually specialised to receive stimuli of a single modality or character. Thus photoreceptors detect light, mechanoreceptors detect mechanical disturbance and chemoreceptors detect specific chemicals. In all cases the sense organs produce a message about the stimulus in the form of nerve impulses which travel up the nerve from the sense organ to the rest of the nervous system. Change of stimulus intensity is usually signalled as a change in frequency of nerve impulses. The position of the sense organ which is active indicates the position of the stimulus within or without the body. The duration of the repeated discharge of nerve impulses indicates the duration of the stimulus.

(ii) Simple Networks

The simplest type of nervous system is the network of interconnected nerve cells (neurones) found in the coelenterates. Branching processes of the nerve cells communicate with neighbouring processes at special regions called synapses. Quite complicated behaviour is possible even with this relatively simple system. If a sea anemone is prodded violently it will close up equally violently, showing that activity has spread throughout the network. If it is tickled gently it will respond with local contractions around the site of stimulation. The movements of feeding and locomotion are very delicately performed at appropriate times.

(iii) Central Nervous Systems

In the majority of animals all the nerve cells tend to become collected into a solid mass of tissue referred to as a central nervous system (CNS). Within the mass the nerve cells are interconnected via synapses in the same way as in a nerve net. The connexions with sense organs and muscles are made via long processes called axons. Numbers of axons are usually bound together with connective tissue to form a nerve trunk. In annelids and arthropods the CNS is seen as a ventral cord lying beneath the gut with a swelling or ganglion in each segment of the body. In molluscs, the ganglia are usually more closely grouped around the oesophagus, with the possible provision of a pair of ganglia further back in the viscera. Vertebrates possess a dorsal nerve cord which is uniform in diameter and not ganglionated, though nerves emerge from it in a segmental fashion. The segmental nerves arise in two separate bundles or roots. The **dorsal root** is made up entirely of sensory nerves conveying information to the CNS. The **ventral root** consists of motor nerves which convey nerve impulses to the muscles of limbs and alimentary canal together with other effector organs such as glands.

(iv) Reflexes

A reflex, in which stimulation of a sense organ or sensory nerve results in the almost immediate contraction of a muscle, is the simplest type of CNS activity. Reflexes have been studied in all animals but the best known ones can be seen in frogs, cats, dogs, and sometimes humans. The very simplest is the stretch reflex, in which a stretched muscle is made to contract by activity coming into the CNS from stretch receptors in the muscle. The activity is relayed directly to the motor neurones of the muscle concerned, making them active and thus causing the muscle to contract. This reflex is monosynaptic, *i.e.* there is only the single synaptic connexion between sensory nerve and motor neurone. The knee jerk in humans is a stretch reflex, the stretch being caused by hitting the muscle tendon as it passes over the knee. Much of the recent work on reflexes has been done on this simple system, notably by Eccles. The flexor reflex, which is seen as the sudden withdrawal of a limb from any painful stimulus, is more complicated. Although the stimuli may vary, the withdrawal response is always accomplished by contraction of flexor muscles which bring the limb in towards the body. The reflex is polysynaptic, *i.e.* several intermediate neurones connect the sensory nerves through to the motor neurones.

More complicated still is the scratch reflex in which an animal is made to scratch its flank in response to an irritation or tickling in that region. This reflex demonstrates some of the more involved properties of the CNS For example a dog will continue to scratch for a time after the tickling has stopped, so that the CNS must continue to be active in the absence of sensory stimulation. This has been called after- discharge.

(v) The Brain

The CNS functions in a more complicated way than is suggested by study of the reflexes and most of these higher activities are co-ordinated by the brain. A greater condensation of neurones is seen at the front end of the CNS of all animals because of the larger numbers of sense organs in that region. Brains, which become the dominant part of the CNS, can be seen in arthropods, molluscs and vertebrates. The close association with sense organs is illustrated by the vertebrate brain which is divided into three regions: (*a*) forebrain (nose), (*b*) midbrain (eye) and (*c*) hindbrain (ear and taste).

However, the brain is very much more than a relay station for these stimulus modalities and it receives information from other parts of the body via the spinal cord. All this information is correlated and activity patterns initiated and transmitted to appropriate regions. In lower vertebrates, the roof of the midbrain (the optic tectum) is the important correlation centre and its effectiveness has been well established in studies on instinct and learning in fish. Another region of the brain of importance in all vertebrates is a dorsal upgrowth of the hindbrain called the cerebellum. This is a motor co-ordinating centre which ensures that all activities are performed in a smooth and well balanced way by the muscles and limbs of the body. In reptiles, the forebrain begins to take over the correlation role and in mammals this development reaches its peak in the cerebral cortex. In man the cortex overshadows the rest of the brain and contains over 1,000,000,000 neurones. It is easy to see the magnitude of the problem of understanding a system of this complexity. The bee's brain with far, far fewer cells can initiate complicated behaviour such as the hive dances. The possibilities offered by the human cortex seem vastly greater, though they are often realised in ways which give cause for concern.

At the moment it is still not possible to build a computer with the properties of the human brain, though the first steps have been taken with the development of 'neural networks' of computers, which display a limited amount of learning and integration skills.

(b) Hormonal Regulation

Many aspects of an animal's metabolism are regulated, not by the nervous system, but by specific chemical signals known as hormones which are circulated in the blood stream. Growth, carbohydrate metabolism, salt balance, activity of ovaries and testes and their associated structures, and colour change are all regulated in some way by hormones. The substances are secreted by endocrine glands or ductless glands as they are often called. The important endocrine glands in vertebrates are the thyroid, parathyroid, adrenal, pancreas, the sex glands, and the pituitary.

In the past the endocrine and nervous systems were regarded as exerting an independent control in slightly different functional areas of the body. It is clear now that the integration of the two systems is much greater than was formerly envisaged and in vertebrates is accomplished through the pituitary gland. Secretions of this gland regulate almost all other endocrine glands and the secretions of the pituitary are either produced in the CNS with which it is directly connected or are controlled by CNS secretions. An astonishing, parallel development of other neurosecretory systems, such as those of the pituitary, has been found in a variety of animals and in all types the neurosecretory organ complex is the dominant endocrine gland of the body. In crustacea the so-called X organ complex found within the eyestalk, and in insects neurosecretory cells connecting to the corpora cardiaca glands, occupy the functional position of the vertebrate pituitary. They all regulate growth, metabolism and reproductive physiology, either directly or through the medication of other endocrine glands.

7. Animal Behaviour

In discussing the nervous system we have already dealt with simple mechanisms such as the reflex. Very much more complicated are the instinctive and learned patterns of behaviour studied by animal psychologists and ethologists.

(a) Instinct

Instinct is inborn behaviour which does not have to be learnt and is usually performed in a stereotyped way. For example a gull will retrieve an egg taken out of its nest by shovelling it back with the underside of its beak. The gull will never replace an egg in its nest in any other way, for example by using a wing or leg, and once it has begun a retrieval it will usually continue the movements back to the nest even though the egg is taken away. An instinctive behaviour pattern is triggered off by a particular stimulus or "releaser" which may be a very small part of the total environment. A male stickleback will attack a very crude model with a red belly but will not attack an exact model without it. The red underside appears to be a much more important stimulus than general shape. A particular instinctive pattern cannot always be elicited and the reaction of an animal very largely depends on when the behaviour was last produced. The longer the time that elapses, the easier it is to trigger off the instinctive pattern until eventually it may appear in the absence of an appropriate set of environmental circumstances.

(b) Learning

Learning is that behaviour acquired during the organism's lifetime as a result of experience. Evidence of learning has been seen in many animals from worms upwards though, as might be expected, the more complicated types of learning are found only in those animals with elaborate nervous systems. A simple type of learning is seen when an animal, upon repeated exposure to a stimulus, gradually decreases the normal response which is usually one of flight, until eventually the response may disappear completely. This process is called habituation. More complex are the *conditioned reflexes*, which were first discovered by Pavlov.

In these an animal can in some way connect a conditioned stimulus such as a bell, with an unconditioned stimulus such as meat, so that eventually it salivates when the bell is rung. Trial and error learning of the type needed to be successful in running a maze is more complicated still. In this there is a retrospective element because the reward at the end of the maze comes after all the responses. Many animals can run mazes and the white rat has been extensively used in experiments of this nature. A final category of learning can be called insight learning; in this an animal shows evidence of resolving a new problem without trial and error.

This type of learning involves the perception of relations between different parts of the environment and though there may be examples in arthropods and molluscs the clearest evidence of it is seen in the behaviour of birds and mammals.

8. Reproduction

A single animal may live for a short or long time, but eventually it dies, and the continuance of the species is dependent upon reproduction. Some protozoa, such as *Amoeba*, reproduce asexually by the simple division of the cell to produce two new individuals. Asexual reproduction also occurs in some coelenterates, such as jelly-fish, in which there is an alternation of sexual and asexual generations. However, the vast majority of animals only reproduce sexually.

This involves the fusion of two cells, the gametes, produced by adult individuals, and each zygote thus formed develops into an individual of the next generation. The gametes are of two kinds, the large, spherical, immobile ova produced by the female gonad or ovary and the much smaller motile sperms produced by the male gonad or testis. The motility of the sperms helps them to reach the passive ovum, which contains food reserves to support the early development of the embryo.

Worms.—The flat worms, particularly parasitic forms, have complicated life cycles, and many are hermaphrodite, *i.e.*, each individual has both male and female organs. Cross-fertilisation usually occurs, the sperms from one worm being introduced into the female duct of another. The round worms are unisexual, and internal fertilisation also occurs. Of the annelids the polychaete worms are unisexual, but the ova and sperms are shed into the sea, where fertilisation takes place. However, *Lumbricus* and the leeches are hermaphrodite, cross-fertilisation takes place and the eggs are laid in cocoons.

Arthropods.—Many crustacea are unisexual, though the sedentary barnacles are hermaphrodite. Internal fertilisation may occur, but in the crabs and crayfish pairing takes place and the sperms are deposited on the tail of the female. When the eggs are shed they become fertilised and remain attached to the abdominal appendages.

Most crustacea have motile larval stages into which the eggs first develop. In *Daphnia*, the water-flea, parthenogenesis sometimes occurs, *i.e.*, the eggs develop without being fertilised. The sexes are separate in the arachnida and there are usually no larval stages except in the primitive king-crabs. The insects are also unisexual, and the fertilised eggs are laid after copulation. In some, *e.g.*, dragon-flies, an immature nymph similar to the adult is formed, but in flies, beetles, moths, and many others the egg hatches into a larval form. This then develops into a pupa, from which the final adult or imago is produced. In the social ant's nest the workers are sterile females with large heads, reduced eyes, and no wings. The males and queens are winged, and insemination of the latter occurs during the "nuptial" flight.

Molluscs and Echinoderms.—Most lamellibranchs are unisexual, although some species of scallops and oysters are hermaphrodite. There are motile larval forms, and in the swan mussel, *Anodonta*, the larvae develop in the mantle cavity of the parent and when liberated become attached to the gills or fins of fish, where they remain parasitic for some time. Some gastropods are unisexual, but the slugs and snails are hermaphrodite. In the latter cross-fertilisation occurs, the two approaching snails being stimulated to copulate by firing small sharp darts of calcium carbonate into each other. The echinoderms are unisexual, and fertilisation takes place in the sea. The egg first develops into a ciliated larval form.

Vertebrates.—The sexes are always separate in the vertebrates. In some cartilaginous fish, *e.g.*, dogfish, internal fertilisation occurs and the eggs are laid in protective sacs. In contrast, the bony fish shed ova and sperms into the water, where fertilisation takes place. Although pairing may take place in amphibia, fertilisation occurs in water, and there is usually an aquatic larval stage. The reptiles, birds, and mammals are independent of water for fertilisation, as copulation takes place and the sperms from the male are introduced directly into the female. Most reptiles and all birds lay eggs with hard shells. Development of the embryo in marsupial mammals begins in the female uterus, but is continued in a ventral pouch which surrounds the teat of the mammary gland. In the two living species of monotreme mammals the eggs are incubated in a similar pouch.

Finally, in the eutherian mammals the embryo develops in the female uterus and is born at an advanced stage.

Diversity of Sexual Reproduction.—This brief survey will give some idea of the diversity of sexual reproduction in animals. External fertilisation is very much a matter of chance, and large numbers of gametes are produced which offset the great losses of gametes and embryos that this method involves. Internal fertilisation is more certain, and is also independent of external water—an important factor in land animals. In vertebrates particularly there is increase in the care of the young by the parents, involving the development of characters of behaviour as well as those of structure. Some fish lay their eggs in holes or nests which are protected by the male. Similarly, a few frogs build nests, while others carry the eggs about.

Eggs of birds require a constant high temperature for their development, and they are usually incubated by the parents. After hatching the young are fed and guarded by the parents until they can leave the nest and fend for themselves. In the eutherian mammals the embryos are attached to the uterus wall by the placenta, *via* which food materials pass from the mother. The period of gestation is long, and after birth the young are supplied with milk from the mother until they are weaned and can feed themselves.

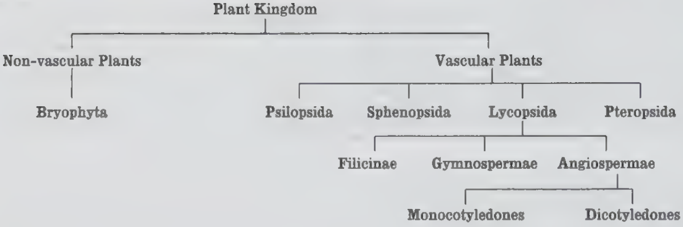
Another feature in mammals is the period of "childhood" during which they play and learn and are protected and fed by their parents. The internal fertilisation, internal development, and care and protection of the young after birth which is so conspicuous in the higher vertebrates results in the reduction of losses during the vulnerable embryonic and young stages, and in consequence relatively few progeny are produced by a pair of individuals.

THE PLANT KINGDOM

There are various ways in which the main classes of the plant kingdom can be grouped, but a simple, up-to-date arrangement is given in the chart. Vascular plants are often known as the *Tracheophyta* because they all possess woody conducting elements. These are absent in non-vascular plants, and the, fungi and algæ are often called *Thallophyta*, *i.e.*, they have a relatively simple plant body or thallus. Many of the bryophytes also possess a thallus, but in some there is a stem bearing leaves, although a true vascular system is absent. Many thallophytes are aquatic, whereas the tracheophytes are mostly land plants in which the development of woody tissues can be related to the attainment of the land habit as the plant kingdom evolved. However, the chart should not be taken as indicating the evolutionary relationships of the various groups. It is more a convenient arrangement which reflects the relative complexity of the plant body.

1. Bryophyta.—These are the liverworts (Hepaticae) and the mosses (Muscineae). They are all small plants characterised by a sharply defined life-cycle. This consists of an alternation of generations, the "plant" being a gametophyte bearing sex organs. The latter are multicellular, the female archegonium containing a single stationary ovum and the male antheridium producing many motile sperms. The latter are released and swim in water to the archegonium, where fertilisation takes place. After this a sporophyte is formed which is always dependent on the gametophyte and never becomes free living. The sporophyte usually consists of an absorbing foot buried in the tissue of the gametophyte and a stalk or seta bearing at the top a single sporangium. In many mosses this is a complex structure with hygroscopic teeth which move apart only when dry, thus releasing the minute spores only when conditions are suitable for their dissemination in the air. The bryophytes are of little economic importance, and may be looked upon as an evolutionary sideline. However, they occupy suitable "niches" in many plant communities, and species of the bog-moss *Sphagnum* cover large areas where rainfall is high.

2. Psilopsida.—This is a small group of primitive, vascular, spore-bearing plants. Its only living representatives are two rare genera of the southern hemisphere. However, a number of fossil forms are known from the Devonian period. The best known are those found in the chert at Rhynie in Scotland. The plants are excellently preserved, and their internal structure can be easily seen.



They were probably marsh plants with prostrate and erect leafless stems, although *Asteroxylon* had simple leaves.

3. Sphenopsida.—The only living members of this group are about twenty-five species of horsetails (*Equisetum*). In the Carboniferous period many tree forms existed (*e.g.*, *Calamites*), the remains of which are very common in coal deposits.

4. Lycopsida.—In the Carboniferous period the tree clubmosses were also prominent members of the forests (*e.g.*, *Lepidodendron*). They often reached 30m in height, were branched or unbranched, and had large simple leaves. They also had extensive root systems. The only living members belong to a few genera of small herbaceous clubmosses, such as *Lycopodium* and *Selaginella*. Like the true mosses, they have an alternation of generations, but the elaborate plant with stem, leaves, and roots is the sporophyte, and the gametophyte is very small. In *Lycopodium* only one kind of spore is produced, and the resultant gametophyte is bisexual. *Selaginella* produces numerous small microspores which give rise to the very reduced male gametophytes and motile sperms and the few large megaspores which produce the female gametophytes. The latter are formed within the megaspore wall, which splits to allow the sperms to reach the small archegonia.

5. Filicinae.—These are the true ferns, which in some classifications are put with the horsetails and clubmosses in the Pteridophyta or vascular cryptogams (*i.e.*, vascular plants without seeds). The ferns have a long fossil history, and remains very similar to the living Royal ferns (*Osmunda*) are known from the Carboniferous. The ferns are widespread and particularly abundant in tropical forests. The majority are herbaceous perennial plants, but a few are aquatic, and there are some tree ferns, which may reach 6 m in height. Most ferns possess a stem bearing roots and large leaves or fronds. The plant is the sporophyte and produces numerous spores in sporangia borne on the fronds. Each spore gives rise to a minute green free-living gametophyte known as the prothallus, which bears the archegonia and antheridia. After fertilisation a young sporophyte develops, which at first draws nourishment from the prothallus. Thus, as in the Bryophyta, external water is essential for the motile sperms to swim in, and there is a clearly defined alternation of generations, but the sporophyte is a complex independent plant, and the gametophyte is reduced though free-living.

6. Gymnospermae.—These were the dominant land plants in the Mesozoic era, although fossil remains are found as far back as the Devonian. The living members still form large forests in the north temperate regions. They are mostly tall evergreen trees with roots, stems, and small leaves. The conifers include the pines (*Pinus*), larches (*Larix*), and yews (*Taxus*). The cycads are a relic group of tropical plants with thick, unbranched trunks and large fern-like leaves. The maiden-hair tree of Japan (*Ginkgo biloba*) has also had a long geological history. Another interesting gymnosperm is *Metasequoia*, a genus well known to palaeobotanists. In 1948 a few living specimens were found in a remote area of China. Seeds were collected and plants are now being grown in botanical gardens all over the world. The gymnosperms are characterised by the production of "naked" seeds, which are usually born on cones. The male pollen grains, which are equivalent to the microspores of *Selaginella*, are carried by wind to the ovule of the female cone. The pollen germinates and the pollen tube carries the male gametes to the reduced archegonia borne on the female prothallus, which, unlike those of the ferns, is retained within the ovule on the parent plant. After fertilisation an embryo is formed, the prothallus becomes the food store or endosperm, and the outer part of the ovule becomes the seed coat. The cycads and *Ginkgo* retain a primitive feature in that the male gametes are motile and they swim to the archegonia from the pollen tube.

7. Angiospermae.—The apparent sudden rise of the angiosperms in the Cretaceous period is still the "abominable mystery" it was to Darwin. Various suggestions have been put forward, but nothing definite is known about the origin of the group. The angiosperms or flowering plants are now the dominant group over most of the land surface of the earth, and at least 250,000 species are known. Apart from the natural vegetation, the majority of our crop and garden plants are angiosperms. They occur in every type of habitat and range in form from gigantic trees to minute plants, such as the duck-weeds. Some are climbers, others succulents, and a number have reverted to the aquatic habit. Although most possess chlorophyll, a few are partial (*e.g.*, mistletoe) or complete parasites (*e.g.*, dodder).

Flower, Fruit and Seeds.—The diagnostic feature of the group is the production of seeds, which are completely enclosed within the female part of the flower, the ovary. Basically a flower is a short reproductive shoot which bears several whorls of lateral organs. At the base are several, often green, protective sepals forming the calyx, and above this are the often brightly coloured petals of the corolla. Within this are the stamens of the androecium or male part of the flower. Centrally is the female gynoecium of one or more carpels containing the ovules. The parts of the flower may be free, as in the buttercup, or fused together. In many species the petals are fused (sympetalous), the stamens are borne on the corolla (epipetalous), and the carpels are fused to form a compound gynoecium (syncarpous). The stamens possess anthers, which produce pollen grains. These are shed and carried by insects or wind to the receptive stigmas of the carpels. Each produces a tube which grows down the style to the ovary and enters an ovule. The ovule is a complex structure containing an ovum and a primary endosperm nucleus. Two male nuclei are discharged from the pollen tube, one fuses with the ovum and the other fuses with the primary endosperm nucleus. After this "double fertilisation" an embryo is formed which is embedded in the nutritive endosperm and the outer tissues of the ovule form the seed coat or testa. The ovary of the carpel develops into the fruit containing the seeds.

Fruits are of various kinds, being either *dehiscent* and opening when mature to release the seeds or *indehiscent*, with a succulent or dry wall. The indehiscent fruits are shed as a whole, and often contain only a single seed. Seeds and fruits show great variation in structure, and often have adaptations assisting dispersal. Some have hairs or wings which aid wind dispersal, whereas others have hooks or are sticky and are transported by animals. Some have flotation devices and may be carried a great distance from the parent plant by water. Seeds vary in size from the microscopic seeds of orchids to those of the double coconut, which may weigh 18 kg. Only about 10% of the weight of a seed is water, and the embryo, although alive, is dormant. The bulk of a seed consists of stored food material, commonly fats or starch and proteins, which may be contained in the endosperm surrounding the embryo, although in some species the endosperm is absorbed during seed development and the food is stored in the one or two swollen seed leaves or cotyledons of the embryo.

Classification of Flowering Plants.—John Ray (1627–1705) was the first botanist to recognise the two great divisions of the angiosperms—the dicotyledons with two seed leaves and the monocotyledons with only one. This primary division of the flowering plants is still recognised. Other differences are also found between the two groups. The dicotyledons usually have net-veined leaves and the floral parts are in fours or fives, whereas the monocotyledons usually have leaves with parallel veins and the floral parts are in threes.

Reclassification of Plants

The world's flowering plants were reclassified in 1998 on the basis of their genetic similarity. Previously, the classification of plants had been largely based on their morphology (physical characteristics). New DNA techniques enabled the study of genetic similarity to be incorporated into plant classification. The more similar the patterns within genes, the more recently two species have diverged.

The New System

The addition of sophisticated genetic analysis has allowed relationships to be clarified and evolutionary patterns to be more clearly understood. The new classification, which draws together several lines of evidence, arranges plants that have evolved from the same ancestor in supra-familial groups, or *clades*. A total of 462 Families and 40 Orders of flowering plants are now recognised.

As a result, it is known, for example, that the lotus flower is more closely related to the plane tree than the water-lily, to which it bears a striking resemblance. Orchids are not related to lilies but to the Hypoxidaceae, or yellow stargrasses. The papaya is related to the cabbage. Roses are related to nettles, blackthorns and figs.

For the first time, there is a true scientific basis for classification; a dataset visible to all researchers.

In 2014 botanists were at last allowed to describe plant species in English instead of Latin.

THE PHYSIOLOGY OF PLANTS

Some of the fundamental differences between animals and plants can be ascribed to the ways in which the two groups of living organisms satisfy their requirements for food material. In a simple way at least, an animal can be thought of as a mobile gastro-intestinal tract which is highly specialised to search out and receive food in convenient, concentrated packets. In typical land plants, however, a quite different organisation exists because the organic nutrition is based on the process of photosynthesis in which carbon dioxide from the air is combined with water from the soil to form simple carbohydrates. An expanded foliage system is necessary to absorb carbon dioxide and to expose the photosynthetic pigment, chlorophyll, to sunlight. Similarly, an expanded root system is needed to absorb the other ingredients of nutrition, water and mineral salts, from the soil. The work of the plant physiologist is to understand the relationships between these two expanded systems of root and shoot.

The Spread of Roots

In addition, the physiologist is concerned with the progressive elaboration of root and shoot as the plant grows. Plants show much less specialisation of their cells into discrete tissues and organs than do animals and they also retain special areas, at root and shoot tips for example, where new cells are added to the structure throughout the life of the plant. In some cases whole plants can be regenerated from very few cells taken almost anywhere from a growing plant body. The orderly regulation of growth and differentiation is thus a basic property of much plant tissue.

1. Movement of Solutes and Water

The movement of water and inorganic solutes in a plant is primarily upwards from the roots where they are absorbed, to the leaves or growing regions where evaporation of water or the use of both water and salts occurs. Water and inorganic ions permeate freely through the cell walls and air spaces of the more peripheral cells of the roots. Equilibrium is established between the insides of cells in this region and the water and salts outside, water tending to enter by osmosis and the salts by diffusion or active transport. Increase in cell volume which would be caused by continual influx of materials is, of course, restricted by the inextensible cell wall. In the centre of the root is a region packed with the specialised conducting tissues called xylem and phloem. These form continuous channels through the root and into the shoot and clearly serve for the conduction of water and substances in solution. In the root this central region is separated from the more peripheral tissue by a single layer of cells, the endodermis. The endodermal layer can actively pump water and salts from the outer regions through into the longitudinal conducting strands of, in this case, the xylem. Evidence for this pumping activity can be seen in the exudation of liquid from the base of a plant stem cut close to ground level. In some cases pressures of 8 to 10 atmospheres have been generated in roots as a result of the pumping action of the endodermal cells.

Transpiration

Water is also moved up a plant by forces generated in the leaves. Constant evaporation from the walls of leaf cells, both on the surface and within the substance of the leaf, causes loss of water from the plant. The process is called transpiration and, within limits, the plant can control transpiration rate by regulating the ease with which water-saturated air passes to the exterior through perforations in the leaf surface called stomata. The diameter of these apertures can be regulated by movements of guard cells surrounding the stomatal openings. Loss of water from the leaf cells is made good by withdrawing more water from the xylem elements within the leaves and stem of the plant. Cohesive forces between water molecules prevent the continuous water columns within the xylem from breaking. The net result is that water is drawn up the stem as transpiration occurs in the leaves. Considerable suction pressures have been measured by suitable manometer systems attached to the cut stems of actively transpiring plants. In addition materials such as dyes or radioactive isotopes have been followed as they move up the conducting xylem vessels at rates which can be related to the rate of transpiration.

2. Movement of Organic Substances

The organic substances, whose site of manufacture is primarily in the leaves, have to be distributed to the rest of the plant body. It is thought that a second conducting tissue, the phloem, is mainly responsible for the distribution of these materials in solution. Ploem is found as a layer of tissue to the outside of the xylem vessels in a plant stem. It consists of conducting cells which are rather different from those of the xylem, which serve, as we have seen, mainly in the transport of water and salts. Whereas xylem tissues are composed of dead cells whose cell walls form effective longitudinal conducting channels, phloem is made up mainly of living cells. Elements called sieve tubes are the most important conducting cells in phloem and, during the initial stages of differentiation, a sieve tube has a full complement of cytoplasm and cell organelles. Later differentiation sees the protoplasmic structures break down, but even in mature sieve tubes protoplasmic strands join through the perforated ends of adjacent cells and may extend longitudinally through the conducting elements.

Ringing experiments in which a complete ring of phloem is cut from the outside of a plant, provide evidence of the tissue's function in longitudinal conduction of carbohydrates. Sugars accumulate above such a ring but not below it. Samples of fluid taken from sieve tubes have also revealed high concentrations of carbohydrates in the sap. The method used to obtain such samples is very ingenious. Several aphids are known which parasitise the phloem translocation channels of plants. The aphid is allowed to insert its stylet tip into the phloem vessels and is then anaesthetised and cut off the inserted stylet. Sap exudes from the stylet stump and can be collected and analysed.

3. Growth

Growth is usually, but not always, thought of as involving increase of size as measured by length, volume, or weight. In these terms any unit in a plant, whether root, shoot or fruit would follow a sigmoid growth curve with growth starting slowly, then speeding up, before finally slowing down at maturity leading on to death. Growth may also be considered as an increase in the number of cells, an increase in substances such as water, protein or DNA in the growing system, or an increase in complexity of organisation.

(*a*) The **organisation of growth**, no matter how it is measured, presents a number of interesting problems. In the first divisions of a fertilised egg, all cells divide. Very soon this property becomes localised, polarity is established, and the young embryo develops a shoot tip and a root tip. These have then become discrete regions of cell division. The cells behind them cease active division, enlarge by developing large vacuoles and form mature plant tissue.

A circular strand of dividing tissue, called the cambium, is left in the stem between differentiated xylem and phloem. The cambium is responsible for growth in girth. The acquisition of polarity has far-reaching consequences, for the behaviour of a shoot tip is very different from that of a root. The shoot tip, for example, gives rise to leaf cells with photosynthesising chloroplasts and it grows upwards away from gravity and towards light. The root tip gives rise to cells which absorb salt and water, and it grows towards gravity and away from light.

(*b*) Quite a lot is known about the **mechanisms which regulate growth** by cell enlargement in the regions behind the actively dividing tips. Cell enlargement is achieved by the secretion of water and solutes to form a substantial vacuole within the cell, thus causing an overall increase of volume and expansion of the cell wall. The degree of enlargement is affected by external stimuli such as light and gravity, producing the differential growth patterns seen when plants orientate to these stimuli. Substances, called plant hormones or auxins, are now known to be produced at the growing apex and to move back causing vacuole formation in the actively elongating region. The distribution of auxin is affected by light or gravity so that the plant will turn towards or away from the stimulus. Indoleacetic acid is the active growth substance occurring naturally in many plants. Several man-made substances are also effective and are widely used as weedkillers. A group of substances exists in plants to control cell division, just as auxins regulate cell enlargement.

Monera, Protista and Fungi

Monera

Monera are simple single-celled organisms lacking a clearly defined nucleus and membrane-bound subcellular organelles such as mitochondria and chloroplasts; they constitute the prokaryotes, or bacteria, archebacteria and blue-green algae. Many authors believe that the archebacteria should be placed in a kingdom of their own. This is a vast group of minute organisms of very simple structure. They are spherical or rod shaped and may exist as separate cells, some species being motile, or as long chains or irregular masses. There is a wall of complex composition, and cytoplasm which contains glycogen and fat. Electron-microscope studies have revealed the presence of structures which appear to consist of nuclear material. Multiplication is by simple division, which may take place very rapidly.

For example, *Bacillus subtilis* can divide every 20 minutes, so that in 8 hours a single cell may give rise to 16 millions. Limited sexual processes also occur. Bacteria can survive unfavourable conditions by producing a resistant spore within the cell. They do not possess chlorophyll, though a few are pigmented. Most obtain their food already formed, and are thus either saprophytes or parasites.

The saprophytic bacteria occupy a vital position in the living world. They are responsible for most of the decay of dead organic matter, and it has been truly said that without them the surface of the earth would soon become completely covered with the dead bodies of animals and plants.

The Role of Bacteria. Bacteria also play a vital part in the circulation of nitrogen in nature. By breaking down organic material, ammonia is released and ammonium carbonate is formed in the soil. This is oxidised by other bacteria to form nitrates, which can be absorbed by plants again. Yet other bacteria can "fix" atmospheric nitrogen, and one species, *Rhizobium leguminosum*, occurs in the root nodules of the pea plant. Such plants are often grown on poor soils and ploughed in, thus improving the fertility of the soil. The parasitic bacteria are also of great importance, as they are responsible for many diseases of plants, animals, and man. Bacteria themselves are the most abundant form of life on our planet and the first to evolve. No other organism is so adaptable.

Protista

This kingdom consists of algae other than the blue-gree algae, along with protozoa and slime moulds. They are mostly unicellular, microscopic, non-vascular organisms; many are motile by virtue of flagella, cilia and pseudopodia.

These are essentially aquatic organisms which contain chlorophyll. They range from microscopic forms to the large seaweeds. The green algae (Chlorophyceae) live mostly in fresh water and may be unicellular, motile or non-motile, or filamentous, though a few found in tropical seas are more complex. The brown algae (Phaeophyceae) are mostly seaweeds which possess a brown pigment, fucoxanthin, which masks the green chlorophyll. They include the bladder-wracks (*Fucus*) and kelps (*Laminaria*) of our coasts and the seaweeds which form dense floating masses over hundreds of square miles of the Sargasso Sea. Another group is the red algae (Rhodophyceae), mostly seaweeds of delicate form, the unicellular motile diatoms (Bacillariophyceae). All algae possess unicellular reproductive organs. Various types of life cycle occur, the most complex is found in the red algae.

Fungi

These are multicellular non-vascular organisms, (forming mycelia with low levels of differentiation into tissues, and more highly differentiated replicative bodies (*e.g.* mushrooms). None contains chlorophyll. Hence, like the bacteria, they are either parasites on other living plants and animals or saprophytes which live on dead organic matter. Some are unicellular aquatic plants, but many have a body called a mycelium composed of many branched threads or hyphæ. In the higher fungi (*e.g.*, toadstools, bracket fungi, and puff-balls) complex reproductive structures are formed which produce spores. In the aquatic species these may be motile, but the majority form minute, airborne spores. The spore output is often very great, and a single mushroom may produce 1,800 million spores. Some fungi are serious diseases of crop plants, such as potato blight and wheat rust. There are an enormous number of species of fungi.

ECOLOGY

Ecosystems

The important branch of biology which deals with the relationship between living organisms and their environment must now be considered. Living organisms and the physical environment in which they exist form what is termed an ecosystem. Obviously it would be possible to regard the whole world as a giant ecosystem, though for purposes of study it would be extremely unrewarding and impractical. A pond, a rocky or sandy shore, a forest, and a peat bog are examples of ecosystems on a somewhat smaller scale, possessing different properties and containing populations of animals and plants that are different both in number of individuals and in species represented.

The ecologist seeks to understand why a particular species is present in certain numbers in an ecosystem in terms of that species' interaction with all other living organisms (*biotic*) and with the physical (*abiotic*) factors of the ecosystem.

1. Abiotic Factors

All living organisms will show ranges of tolerance for abiotic factors such as temperature, humidity, salinity, oxygen levels, amount of light, etc. Clearly, if any factor in the environment moves outside the range of tolerance of a species, it becomes limiting for that particular species which is then excluded from the environment. Within the range of tolerance there will be an optimum value for each abiotic factor at which a species will survive best.

There is not a firm line separating suitable and unsuitable environments, but rather a steady shift from optimum values into conditions in which an organism finds it more and more difficult to survive.

One of the most important abiotic factors in an environment is the nature of the substrate upon or within which an organism moves and settles.

(*a*) **The Terrestrial Environment.**—Soil is the commonest substrate for terrestrial organisms. Particle sizes, ranging from the coarsest gravel soils, through sands and silts to the finely textured clays, have extensive effects on the flora and fauna of any area. Coarsely textured soils are obviously penetrated most easily both by roots and by soil animals. Soils of this type also allow the rapid movement of water and soil gases, but they have the serious disadvantage of poor water retention. The level at which water saturation occurs is known as the water table and is an important abiotic factor. The terrestrial environment tends on the whole to dehydrate organisms and there is always a marked dependence on water supplies.

Soil characteristics also vary with depth. A vertical section through any soil is referred to as its profile and has considerable bearing on the ecosystems in which the soil is involved. The layers, or horizons, of a soil profile vary enormously from one soil to another. Below a surface layer of organic debris one can, in general terms, distinguish a layer of soil from which substances have been leached (A horizon), soil containing the leached-out substances from the layer above (B horizon), the weathered parent material (C horizon), and finally the parent rock or some other stratum beneath the soil (D horizon).

Humus, which is formed from animal and plant remains is of great importance in providing food for soil organisms and chemical elements such as nitrogen, phosphorus, and calcium for plant growth. It is also important in maintaining good soil structure and, though inorganic fertilisers can supply chemical elements, they have little or no effect on structure. Soil requires careful cultivation, and structure is easily disturbed by such things as heavy farm machinery, which can lead to the creation of impermeable layers with the disastrous exclusion of oxygen and oxygen-consuming organisms.

(*b*) **The Aquatic Environments.**—Marine and freshwater environments together cover more than 75 per cent of the earth's surface and, since they can be occupied throughout their entire depth, offer a much greater volume of living space than does the land. There is only a slight difference between the density of water and of living tissues, so that the bodies of aquatic organisms are very largely supported by the environment and do not need strong woody stems or powerfully muscled limbs to hold them up. Water has a high specific heat, which means that large amounts of heat are needed to raise its temperature. The result is that aquatic environments tend to show much smaller fluctuations in temperature than the terrestrial ones. In general, the larger the volume of water the smaller are the fluctuations in temperature, and so the fauna and flora of the oceans will not show wide temperature tolerance, whereas that of small pools will, but in neither case will the tolerance be so great as that shown by many terrestrial forms. Oxygen and carbon dioxide concentrations are very different in water and in air and are also variable from one aquatic environment to another, making them suitable for the support of different fauna and flora.

Salt Concentration

An important difference between the sea and freshwater is seen when their salt concentrations are determined. Organisms in fresh or in sea water face quite dissimilar problems in osmotic and ionic regulation. Life evolved originally in the sea and the salt concentration in the blood of marine molluscs, crustaceans, and echinoderms, for example, is about the same as in sea water itself. Marine organisms have, on several occasions in the course of their evolution, moved into freshwater. Representatives of the worms, crustaceans, molluscs, and vertebrates have all independently invaded this very dilute habitat. What is more, all these animals show approximately the same types of modification to cope with the change. Their outer layers, in the main, become impermeable and the salt concentration of their blood is reduced considerably and to a spectacularly low level in the freshwater mussel. The kidneys become enlarged and produce a large volume of dilute urine. By these means freshwater animals can cut down loss of their salts. It is interesting that all terrestrial vertebrates, including the mammals have retained a salt concentration in their blood of about half the seawater level and this is partly attributable to their freshwater ancestry. The ultimate development of salinity tolerance is seen in such animals as the salmon and eel which move from fresh to salt water and back again during their life cycle.

2. Biotic Factors

(*a*) **Associations between Organisms.**—No organism can be considered to be independent of any other organism in an ecosystem but in some cases close associations of various types can be developed between different species or different members of the same species.

Commensalism is an association which benefits one member but has little effect on the other. Small organisms can live within the protective covering offered by a larger individual, as, for example, commensal crabs living within the shell of some species of oyster.

Symbiosis is a somewhat closer association in which both members benefit, as do certain species of green algae and the coelenterates in whose body tissues they live. The algae are protected and the coelenterates benefit from the food produced by the photosynthetic plant. Some symbiotic organisms are unable to survive outside the association. The lichens which are associations of algae and fungi, are examples of this type of symbiosis, as are some of the food-processing micro-organisms together with the animals in whose intestinal tracts they live.

Social Animals. In some cases animals of the same species form social groups in which co-operative effort and division of labour makes them more successful in exploiting a particular environment. Social development is most obvious among certain insects such as termites, ants, wasps, and bees, and among the vertebrates. Social organisation in these groups may lead to the development of different behaviour patterns and ultimately, as in ants and bees, for example, to the evolution of a variety of structural modifications so that different castes are recognisable.

Parasitism. Not all associations are of mutual benefit and when one organism becomes sufficiently specialised so that it can live successfully on materials extracted from another, the latter is always adversely affected. Parasites, by causing disease in, and sometimes the death of, the host, can influence population growth and size. Important groups are bacteria, protozoa, fungi, nematodes (roundworms), and platyhelminths (tapeworms and liver flukes). Viruses are also important disease-producing agents which are incapable of an independent existence outside the cells of the host and utilise the host cell's metabolic pathways directly to synthesise new virus material.

Control of Parasites. Many parasites (and other pests which may disturb the comfort and health of man) can now be controlled to some extent, and, for a variety of reasons, such control procedures have extensive effects on the ecosystems involved. The regulation of some bacterial parasites by means of antibiotics, and control of the insect vectors of organisms such as the malaria parasite by means of insecticides, have both been important factors in the increase in human population. Though the beneficial effects of pest control of all types are clear, the process is not without its difficulties and dangers. Indiscriminate use of many chemical agents has led to the development of resistant strains. In any group of organisms, some will naturally be more resistant to a pesticide or antibiotic than others and these will be the survivors of any treatment that is less than totally effective. They will form the breeding stock for subsequent generations and so progressively more and more resistant types will evolve. Thus, there are now many strains of bacteria resistant to penicillin and other antibiotics.

Parasite Resistance. Even more alarming is the recent discovery that this resistance can be transferred in an infective way between bacteria of different species. Another complication associated with chemical control is that the agent concerned frequently affects a wide spectrum of organisms, including those that are in no sense injurious to man or his crops. Thus DDT kills bees and other pollinating insects unless its application to a crop is very precisely timed. In addition, the accumulation of quantities of chlorinated hydrocarbons such as DDT in the environment is known to have an injurious effect on organisms other than insects. Because these chemicals are broken down very slowly they now form a serious problem in environmental pollution.

Specific Pesticides. Agents such as DDT are now being replaced with much more specific pesticides which inhibit particular stages of development of particular species of pests, *i.e.* growth regulators. Biological control is also becoming much more widely used, and is based on introduction of species which are specific predators of local pest populations.

(*b*) **The Food Factor.** -Plants are the ultimate source of organic food for all animals. The most important food plants are those capable of *photosynthesis* in which organic material is synthesised from carbon dioxide and water, using radiant energy from the sun to drive the reaction. Plants are eaten by herbivores which in turn are eaten by carnivores. It is possible to see many such sequences, called food chains, in all ecosystems.

MOLECULAR BIOLOGY
GLOSSARY OF KEY TERMS

Biotechnology A set of methods for using living organisms to make a variety of products, including alcoholic drinks, bread and medical drugs.

Blotting A method of detecting specific nucleic acid sequences. A mixture of molecules is separated by size on a gel made of agarose, and a filter made of nylon or nitrocellulose is then placed on the gel, so that the nucleic acid molecules bind irreversibly to the filter. A nucleic acid of known sequence, which has been radioactively labelled, is then incubated with the filter so that the labelled nucleic acid sticks ("hybridises") with molecules of complementary sequence attached to the filter, so that the latter can be detected and the size can be measured. When DNA is attached to the filter, the procedure is called Southern blotting after its inventor; when RNA is attached to the filter, it is called Northern blotting. A similar method exists for proteins, using antibodies to detect specific proteins, which is called Western blotting.

cDNA An abbreviation for complementary DNA, which is a DNA "copy" of an mRNA molecule extracted from a cell; this is often the first step in cloning a gene, and is carried out using reverse transcriptase.

Chromosomes Chromosomes are structures found in the nuclei of plant and animal cells and consist of the cell's DNA, along with a number of specialised proteins. The functions of the chromosome are to minimise the space occupied by the DNA—in mammalian cells, up to 2 m of DNA has to be packed into a nucleus only 4–10 μm in diameter—and to distribute newly synthesised DNA to the daughter cells after cell division. Somatic cells (*i.e.* cells not specialising in reproduction) of different species contain different numbers of chromosomes, *e.g.* man (46), cat (38), mouse (40), honey bee (16), *Drosophila* fruit fly (8), and potato (8). The chromosomes in each case consist of 2 sets of paired chromosomes; reproductive cells contain only 1 set of chromosomes, and are thus described as haploid. Bacteria contain a single chromosome, which is much simpler than the chromosomes of higher organisms, and is circular.

Cloning The production of genetically identical copies of a biological material, for example starting from a single cell. In recombinant DNA technology, cloning consists of joining a DNA molecule to a vector (*q.v.*) and putting the resulting recombinant molecule into a bacterium, where the vector then allows large quantities of the DNA molecule of interest to be made.

Cytoplasm *See* **T32.**

Denaturation In general, the breakup of the higher structure of a biological polymer. For example, egg white becomes opaque on cooking because of denaturation of the protein albumin, caused by heat. In nucleic acids, denaturation refers to the breakage of the hydrogen bonds between the nucleotide bases that hold the two strands of a double-stranded DNA molecule together: heating a double-stranded molecule causes the two strands to separate (this is also called "melting"). If a solution of denatured DNA molecules is allowed to cool slowly enough for the separated strands to bump into each other, the double helix re-forms; this is called renaturation, and only occurs when the base sequences of two DNA molecules are complementary to each other (*see* **Nucleic Acids**). Double-stranded molecules consisting of one DNA strand and one RNA strand ("heteroduplexes") can also be formed by this method.

Deoxyribonucleic Acid (DNA) *See* **Nucleic Acid, T47.**

DNA Fingerprinting DNA fingerprinting consists of examining repetitive DNA in the genome for variations in the lengths of restriction fragments. The DNA from the genome is cut with a restriction enzyme known to cut repetitive sequences into short pieces and is then used in blotting experiments using probes that hybridise to the repetitive sequences. Every individual has his own pattern, so that fingerprinting can match blood to a particular person, and patterns are inherited from parent to child, allowing the method to identify relationships between individuals.

Exon *See* **Intron, T47.**

Gene A unit of genetic information, *i.e.* the DNA sequence encoding one protein or RNA gene product.

Gene Expression The process of making a product (protein or RNA) from a gene. Regardless of the gene product, the first step consists of transcribing the DNA to make an RNA copy; this can be the final product, or it can be translated to make a protein molecule.

Gene Product When the information in a gene is copied, the final product is either a protein or an RNA molecule. The term gene product includes both of these. It does not usually include messenger RNA (mRNA), which is an intermediate between the DNA of the gene and the final protein.

Genetic Code Sequence information in genes is used to specify amino acid sequences in proteins. There are four bases in nucleic acids and 20 amino acids in proteins, so a direct one-to-one correspondence is not possible. Groups of two bases could only store information about eight amino acids. Three bases (a "codon") can store information about 64 amino acids; this is the code that is used. Since there are only 20 amino acids in proteins, the code is quite redundant, most amino acids being represented by 2, 3 or 4 different codons, though these codons are generally related, *e.g.* GGA, GGT, GGC, and GGG all encode the amino acid glycine. Three of the 64 codons have the special function of telling ribosomes that the protein it is making has come to an end; these are called "stop codons".

Genetic Disease A disease caused by a defect in a gene (*i.e.* a mutation) or in a chromosome. A well known example of a genetic disease caused by a point mutation is cystic fibrosis. Some types of leukaemia are associated with a chromosomal defect, where the long arms of chromosome 21 are shorter than normal (this is called the Philadelphia chromosome).

Genetic Diversity The number of different *alleles* in a population. An *allele* is an individual's version of a particular gene, so the larger and more varied a population, the more different versions of a given gene it will contain, and the greater will be its genetic diversity. The importance of genetic diversity is that a larger allele pool makes a species better able to adapt to changing conditions.

Genome The total set of genetic information in an organism. Physically, the genome corresponds to the sum of all the chromosomes in a cell, *i.e.* all the DNA that the cell contains. The genome thus consists of all the genes encoding proteins and RNA molecules, as well as large amounts of non-coding or silent DNA. Much of this is made of repeated DNA sequences, which can be classified into a number of families.

Haploid Most animal cells contain two pairs of chromosomes—one from the father and one from the mother, and are called *diploid.* Reproductive cells (spermatozoa and oocytes) contain only one set of chromosomes and are called *haploid.* When a spermatozoon and an oocyte fuse, the resulting cell becomes diploid and develops into a new animal. A similar process occurs in plants.

Human Genome Project *See* **Section L.**

In vitro Used of an experiment that is not carried out in a living body.

In vivo Used of an experiment carried out in a living body.

Intron The nucleic acid sequence of a gene is often much longer than needed to encode the protein or RNA product of that gene. The part of the gene containing protein-encoding information is found to be split up into sometimes numerous small pieces called exons, which are separated by non-coding pieces called introns. Transcription produces an RNA copy (a pre-mRNA) containing both exon and intron sequences. Before the mRNA migrates out of the nucleus, the parts of the pre-mRNA corresponding to the introns are removed, a process called splicing.

Ligase An enzyme that is used in recombinant DNA technology for joining the ends of two DNA molecules together, usually after renaturation of sticky ends. Ligase is involved in the replication and repair of DNA.

mRNA An RNA molecule that is a copy of the base sequence of a gene, and carries that sequence from the nucleus to the cytoplasm to instruct the ribosomes to make a protein of the correct amino acid sequence.

Mutation A change in the sequence of bases in a gene. This can be a change from one base to another (point mutation), or loss or addition of one or more bases from or to a gene sequence (deletions and insertions respectively). Changes which do not alter the structure of the gene product, *e.g.* mutations in exons and mutations in codons that do not alter the amino acid encoded by those codons, are called silent mutations.

Nucleic Acids Biological polymers consisting of a chain of sugars joined by phosphate groups, where each sugar carries a nucleotide base. There are two important nucleic acids, deoxyribonucleic acid (DNA), which is the chemical of which genes are made in most organisms, and ribonucleic acid (RNA), of which three types (mRNA, rRNA and tRNA) are involved in protein synthesis; some viruses carry their genes in the form of RNA. Nucleic acids store information in the sequence of chemical bases attached to the sugars; the bases in DNA are adenine (A), thymine (T), cytosine (C) and guanine (G), while those in RNA are the same except that uracil (U) replaces thymine. The two ends of a nucleic acid molecule are different; one is called the 5′-end and the other is called the 3′-end. DNA is usually double-stranded; that is, two DNA molecules are linked together side by side and pointing in opposite directions as a double helix, joined by hydrogen bonds between the bases, which point towards the centre of the helix. Because of the chemical structures of the bases, C can only form hydrogen bonds with G and vice versa, T and U can only form bonds with A, while A forms hydrogen bonds with T in DNA and with U in RNA. Thus, if the sequence of bases in one of the two strands in a double-stranded DNA molecule is 5′-CATTG-3′, the "complementary" sequence in the other strand will be 3′-GTAAC-5′. The RNA sequence complementary to this DNA sequence will be 3′-GUAAC-5′. Two molecules that have similar sequences are said to be homologous.

Nucleolus A structure within the nucleus, consisting of copies of the cell's ribosomal RNA genes, which are sometimes needed in larger numbers than can be provided within the chromosomes, *i.e.* when cells have to synthesise large quantities of protein and thus need large numbers of ribosomes.

Nucleotides Nitrogen-containing bases attached to a sugar phosphate. *See* **Nucleic Acids.**

Oligonucleotides Very short nucleic acid molecules. Oligonucleotides are often used as the probes in blotting studies and other recombinant DNA techniques because oligonucleotides of known sequences can easily be made in the laboratory.

Oncogenes A number of cancers have been found to be caused by viruses. The ability of a virus to cause cancer is conferred upon it by special genes, which are called oncogenes. Oncogenes are usually related to normal cellular genes involved in regulation of cell growth, and cancer due to oncogenes can be thought of as resulting from the abnormal expression of a normal gene.

Peptides Very short proteins.

Plasmid A small circular DNA molecule containing a replication origin (it is thus a replicon) commonly found in bacteria. Plasmids are widely used in recombinant DNA technology as vectors for cloning DNA fragments because of their small size. In nature, plasmids are responsible for a considerable proportion of bacterial antibiotic resistance—moving from cell to cell, they carry antibiotic resistance genes with them.

Polymerase Chain Reaction (**PCR**) A method for synthesizing relatively large amounts of a nucleic acid of known sequence, using polymerase enzymes and oligonucleotides.

Proteins Biological polymers made of amino acids, of which 20 are used in living organisms. The properties of a particular protein depend on the sequence of amino acids of which it is made, and this sequence is determined by the sequence of nucleotide bases in the gene corresponding to the protein. Proteins can be structural (*e.g.* collagen) or they can be enzymes, which catalyse chemical reactions. Some proteins, such as haemoglobin, have the special function of transporting other chemicals around the body.

Recombinant DNA Technology A more precise term for genetic engineering.

Repetitive Sequences Much of the DNA in the genome of a higher organism does not contain genes, but consists of apparently functionless sequences, some of which are repeated head-to-tail. Genomes contain a number of families of related repeats, and up to 20% of the genome can consist of sequences present at up to 1,000,000 repeated copies.

Replicon A DNA molecule that is able to replicate in a cell. In order to do this, the molecule needs to carry a special sequence called a replication origin, which is the point at which synthesis of new copies of the DNA begins.

Restriction Endonucleases Enzymes found in bacteria that cut DNA molecules; their function is to protect bacteria against infection from viruses. Class II restriction enzymes, the group which is important in recombinant DNA techniques, bind to a short (usually 4 or 6 bases) sequence and cut the DNA in or close to the recognition sequence. Bacteria protect themselves against their own restriction enzymes by chemically modifying their DNA. Restriction enzymes allow DNA molecules whose sequences are known to be cut at predetermined positions. Many enzymes cut the two strands of a DNA molecule in slightly different places, to leave single-stranded overhangs ("sticky ends"); these can be renatured to join pieces of DNA together in a specific way.

Retrovirus A virus which stores its genetic information in the form of RNA instead of DNA; several are tumour-inducing viruses, and the viruses associated with AIDS are retroviruses. Replication of these viruses starts with making a DNA copy of the RNA genome, using the enzyme reverse transcriptase.

Reverse Transcriptase A viral enzyme found in some viruses that use RNA instead of DNA for their genomes. This enzyme is an RNA-dependent DNA polymerase, and makes a DNA copy of the viral RNA, which is the first step in the replication of such viruses.

Ribonucleic Acid (RNA) *See* **Nucleic Acids.**

Splicing *See* **Intron.**

Transcription The process of copying a DNA molecule to make a complementary RNA copy of a gene. Transcription occurs in the nucleus of higher organism cells, and is carried out by enzymes called DNA-dependent RNA polymerases.

Transgene A foreign gene inserted into a higher organism (animal or plant). This is done by inserting the gene into the organism at an early stage of embryonic development; since all the cells of the adult come from these early embryo cells, all adult cells will contain the inserted gene. Such organisms are called transgenic animals or plants.

Translation The process of converting a gene sequence in the form of mRNA into a protein sequence. Translation is carried out by ribosomes.

Vector In recombinant DNA technology, a replicon that is used for cloning DNA sequences. Vectors are usually small and simple replicons, *i.e.* plasmids and bacteriophages.

V. HUMAN EVOLUTION

Introduction

Although the broad pattern of human evolution is the subject of agreement amongst scientists, almost all the details are contentious. The exact relationship to one another of successive species, for example, is very uncertain and the family tree of modern man is constantly being revised as new evidence and new dating techniques become available.

As just one example, scientists long argued over the fate of 'Neanderthal Man'. Did he evolve with exceptional speed into a modern human, was he conquered and eliminated by modern man, or did he interbreed and lose his distinctive characteristics in the process?

International research into the genetic code of 'Neanderthal Man', the results of which were published in 2010, has, however now established that between 1 and 4 per cent of the DNA of modern non-African humans is Neanderthal in origin. In other words, the first humans to migrate out of their African homeland interbred with the Neanderthals they met, probably in the Middle East some 100,000–50,000 years ago, and in due course carried that genetic material on to Europe, Asia and Australasia.

The story of human evolution is complex as well as contentious and readers may find the following chronology helpful as a brief introduction.

A Note on Terms

Neither scientific nor popular literature is consistent in the use of such words as 'hominid' and 'human'. 'Hominid' can be used as a comprehensive descriptiom for the biological family of two-legged primates as a whole, but is more normally restricted to the human lineage only, and that practice has been followed here. Some authorities, however, prefer the term 'hominin' to describe the earliest members of the human family such as the Australopithecines.

The description 'human' is particularly fluid, but is most conveniently applied to hominids who had evolved towards making tools and enjoying some form of social life.

CHRONOLOGICAL TABLE

Years BCE	
70 million	The emergence of the primates, the order of mammal to which all humans, apes and monkeys belong.
25 million	The emergence of the biological family which currently comprises the four genera of chimpanzee, gorilla, orangutan, and human (genus homo). The earliest representative, identified in the Fayum, Egypt, known scientfically as *Aegyptopithecus zeuxis* and colloquially as the 'dawn ape', lived in trees and was the size of the modern domestic cat.
25–8 million	The evolution of more than 50 species who were descended from *Aegyptopithecus*, of which one, *Proconsul africanus*, is believed to be the ancestor of modern apes and humans.
20 million	The evolutionary line of the ape diverges from that of the monkey.
18 million	*Proconsul africanus*, the size of the modern baboon and living in trees, speads over East Africa.
5 million	The likely divergence of the human from the chimpanzee evolutionary line.

3·7–1·6 million	The earliest identified hominids (*i.e.* members of the genus *homo*), the Australopithecines, comprising four distinct species. One, the lightly built *australopithecus africanus*, or *gracile* australopithecine, is likely to be the ancestor of modern man. Their remains have been found in Ethiopia, Kenya and South Africa. The 'Laetoli footprints' (*see* **T53(2)**) established that the australopithecine was fully bipedal (*i.e.* walking on two legs). This had enabled its forelimbs to develop into arms and hands, permitting the carrying of food over distances, the making of tools and weapons, and the nurturing of children.
2·1–1·7 million	The emergence of *homo habilis*, the first hominid known to have used tools. The distribution of remains parallels that of the australopithecines.
1·6 million	The emergence of *homo erectus*, generally, but not universally, accepted as the ancestor of modern man. Remains have been found in north and east Africa, Europe, Indonesia and China. It survived, at least in China, until as late as 300,000 years ago. Java Man and Peking Man are popular names for the remains found in those places.
1·2–1·1 million	Pioneer man (*homo antecessor*) is active in Spain. Although he used tools, he is not thought to be a direct ancestor of modern man (*homo sapiens*).
990–780,000	The first evidence of man in Britain (Happisburgh, Norfolk). Probably of *homo antecessor*.
560,000	A tooth dating back this far discovered at the Tautavel prehistoric site in France.
500,000	The earliest human remains found in Britain (Boxgrove, West Sussex). Probably of 'Heidelberg Man', an archaic human, who is likely to have been the direct ancestor of modern man, *homo sapiens*, and of whom remains are widespread.
440–270,000	Modern man (*homo sapiens*) and 'Neanderthal Man' start to evolve as separate species from a common ancestor, believed to be 'Heidelberg Man'.
200–150,000	Final evolution, in sub-Saharan Africa, of modern man, *homo sapiens*.
70,000	Modern man migrates out of sub-Saharan Africa (perhaps very much earlier). Human teeth over 80,000 years old have been found in China.
50,000	The migration of modern man extends as far as Australia. The skeleton of Mungo Man (*c.* 42,000 years old). World's oldest axe, dating back 49,000 years, found in Western Australia. The primitive *Homo floresiensis* is wiped out.
35,000	The earliest known figurative art (a 'pornographic' female figurine – the Venus of Höhle Fels – found in Germany). Earliest cave paintings date to this time.
30,000	'Neanderthal Man' very probably becomes extinct as a species.
13,200	The earliest evidence yet found of modern man in the Americas (footprints in British Columbia, Canada). As glaciers retreated early humans followed the bison herds.

THE EMERGENCE OF MAN

New discoveries are constantly causing our views on the fascinating story of human evolution to be revised. The recent find of Sahel Man in Chad, a 'missing link' provisionally dated to *c.* 7,000,000 B.C. could suggest that the very first hominids did not develop in the Rift Valley of Kenya and Ethiopia (often called the Cradle of Civilisation) but in fact 1,500 miles west. Even more exciting and problematic were the discoveries made in caves in South Africa (*see* **Postscript T55(2)**).

Likewise the discovery in 2006 in Ethiopia of the remains of the earliest known child (nicknamed Selam and 'Little Lucy') has begun to unearth new evidence of the link between apes and humans.

Similarly, the widely-reported discovery of the 'Hobbit', the skeleton of a new and completely unexpected species of tiny humans on the remote Indonesian island of Flores, suggests that this very small metre-tall human shared the planet with other humans around 18,000 years ago – not long before the dawn of recorded history.

Systematics

The study of systematics (*q.v.*) shows us that the relationships which form the basic structure of zoological classification set every species in the context of a greater whole—genus, family, order, and so on. *Homo sapiens* is no exception. Man is not the end-product of the entire evolutionary process, as is commonly supposed. On the contrary, man's place in nature is at the end of a relatively short line radiating from among the millions which have evolved since life on Earth began.

The Origin of the Primates

The primates are essentially tropical animals. With the exception of humans, virtually all living species are arboreal, and 80 per cent of them are found in the tropical rain forests. Their most distinctive characteristic is the very general and unspecialised nature of their anatomical structure, and the highly specialised and adaptable nature of their behaviour. While other mammals evolved specialised physical characteristics (the giraffe's long neck, for example), the primates have retained the basic structure of the ancestral mammalian form and have instead adapted their behaviour to suit prevailing circumstances. The human hand is a case in point—it has the same number of bones operated by the same arrangement of muscles as the arboreal primates possessed 45 million years ago, yet the human hand serves a much greater variety of uses.

Early Fossil Evidence

The fossil evidence indicates that primates have existed for at least 70 million years. They were one of the groups of placental mammals which survived the mass-extinction event which closed the Cretaceous period of geological time, about 65 million years ago. The dinosaurs were among those which disappeared with that event, and their passing marks the end of the epoch known as the age of the reptiles. Some reptiles survived, of course, but with the declining prominence of the dinosaurs the mammals flourished, heralding the age of the mammals with a burst of adaptive radiation which eventually took them into every ecological niche which the dinosaurs had previously occupied.

The Early Mammals

The early mammals had lived in the shadow of the dinosaurs for more than 100 million years before the Age of the Reptiles came to a close. They were small (typically about 10 cm long), and occupied parts of the environment that the large reptiles could not reach—the nocturnal world, for instance, (a temporal dimension in which the cold-blooded reptiles could not function), and rocky crags, holes and forest undergrowth. Here they evolved a high degree of sensory perception. Sight, sound, touch and smell assisted their capture of the invertebrate prey upon which they largely subsisted; integration of cerebral and physical equipment was crucial, and while the later evolution of the dinosaurs was concerned primarily with physical structure, that of the early mammals was concerned with the development of brain and behaviour. This equipped them well for the radiation which followed.

Of the various habitats available to the mammals as the age of the reptiles drew to a close, the ancestors of the primates took to the trees. Here they found a rich and varied diet—leaves, buds, fruit, insects, birds' eggs and nestlings—but also a suite of new demands. Life in the trees called for a shift in the emphasis of the mammals' environmental awareness. While the nose had probably been the most important organ of ground-dwelling mammals, the eyes were more crucial in the trees.

The Development of Arboreal Mammals

Because a tree is a spatially restricted environment, an arboreal animal needs to be particularly aware of its whereabouts. It must know if a potential predator is in the same tree, and if a fruit is at the end of a safe branch. It must be able to see clearly and judge distances accurately as it moves through the branches. These requirements favoured the evolution of stereoscopic vision, which was further enhanced by the advent of colour vision.

Life in the branches also called for greater agility. An ability to flex the paws and grasp things was advantageous; digits evolved into fingers, claws into fingernails. Front limbs became principally a means of holding on, while the rear limbs served as a means of propulsion and also of static support. Thus the animals could leap safely about the trees, and also could sit with the spine erect, the head turning with a perceptive eye, the ears twitching.

It can be supposed that the attributes favouring an arboreal existence also promoted yet more cerebral development. A large brain relative to body size evolved; accommodating a larger brain required some restructuring of the skull, which in turn was affected by the masticatory demands of the foods which the animals ate—fruit, leaves, insects, meat.

Such an omnivorous diet calls for neither the specialised canines and slicing teeth of the carnivores, nor the grinding molars of the herbivores. The ancestral set of general all-purpose teeth was retained. The jaws broadened and shortened, the face flattened, the eyes looked forward and the expanding brain took up more and more room at the back of the skull. These interactive and interdependent features evolved over millions of years, a mosaic of cause and effect from which evolved the order of mammals known as the primates.

In basic zoological terms, the primates which evolved from the early arboreal mammals are distinguished from all other placental mammals by the fact that they have retained the four kinds of teeth found in ancestral mammals (incisors, canines, premolars and molars); they can hold things between finger and thumb, they have frontally directed eyes and have a large brain, relative to body size. They are represented today by 193 living species, all but one of which are covered with hair.

Hominid Ancestry

The broadest categories of the primate order were also the earliest to have existed in evolutionary time, and the divisions were created principally by the geographic isolation resulting from the breakup of Gondwanaland, the supercontinent on which the primates had originated. Thus, the tarsier suborder became confined to the islands of Indonesia and the Philippines, and the prosimian suborder is best represented today by the lemurs of Madagascar, where the infraorder has been isolated for close on 60 million years. Another infraorder of prosimian, represented by the pottos, lorises and bushbabies, remained on continental Africa and Asia, and has found isolation in a nocturnal way of life as other primates adopted a diurnal lifestyle.

Isolation similarly split the anthropoid suborder when the landmass of South America broke away from Gondwanaland about 40 million years ago, carrying with it the primate stock which evolved into the platyrrhines—the New World monkeys. Subsequently, the catarrhine stock left on Gondwanaland split into its two main groups, probably along the lines of diverging dietary preferences. One group adopted a mainly herbivorous diet and gave rise to the Old World monkeys or cercopithecoids (represented today by the baboons and the colobines), while the other retained a more omnivorous diet and produced the hominoids (gibbons, apes and humans).

Dating the Hominid Line

The precise dates at which these splits occurred are uncertain, but the fossil evidence suggests that the hominid line is at least 25 million years old. A putative ancestor from that time has been found in the Fayum, south west of Cairo. The land is arid desert now, but 25 million years ago it was tropical rain forest and swampland, laced with broad meandering rivers. Scientists excavating fossil beds in the region have recovered the remains of a creature which is described formally as *Aegyptopithecus zeuxis*, though it is more colloquially known as the "dawn ape". Jaws and teeth, a skull and the skeletal parts of several individuals suggest that *Aegyptopithecus* was diverse and very generalised in its physical form. Experts have reconstructed from the fossil evidence a picture of a small arboreal primate, about the size of a domestic cat, with a sinuous back, long limbs, and all four feet capable of both grasping branches and conveying food to the mouth. The eyes looked forward, indicating stereoscopic vision, and the brain was larger in proportion to bodyweight than any other mammal.

Early Species

The descendants of *Aegyptopithecus* and its kind appear to have been very successful in evolutionary terms. More than 50 species are known from the fossil record, and hence palaeoanthropologists are inclined to refer to the Miocene (the geological period extending from 26 million to 8 million years ago) as the age of the ape. One of these species, *Proconsul africanus*, is believed to represent the line which led to the modern apes and humans.

First described from a nearly complete face and partial skull discovered by Mary Leakey on Kenya's Rusinga Island, Lake Victoria, in 1948, *Proconsul* was a tree-dwelling animal about the size of a baboon which roamed East Africa about 18 million years ago, sometime after the monkey and ape lines had diverged. More remains were recovered during the 1970s, enabling scientists to reconstruct a skeleton that was essentially 75 percent complete. The result showed an unexpected mixture of characteristics. *Proconsul* had a backbone resembling that of the gibbon, shoulder and elbow joints like those of the chimpanzee, and the wrists of a monkey. Overall, *Proconsul* is quite unlike any living ape, but could be ancestral.

Migration from Africa

Around 17 million years ago, the African continental plate butted up against Europe, raising high mountains and creating a landbridge across which many African animals migrated into Eurasia for the first time. Among them were apes whose fossil remains have also been proposed as candidates for the ancestry of the ape and human lines. *Dryopithecus* was found in Greece, *Ramapithecus* and *Sivapithecus* in the Siwalik Hills of northern Pakistan. The fossil evidence was fragmentary, but for many years *Ramapithecus*, dating from 14 million to 7 million years ago, was almost universally accepted as the earliest known ancestor of the human line. During the early 1980s, however, the discovery of more complete ramapithecine remains showed that it and the sivapithecines are more likely to represent ancestors of the orang-utan on their evolutionary and migratory journey to the south-east Asian islands where they are found today. Consensus opinion now rates the dryopithecines as close cousins headed for extinction, and regards Africa as the cradle of mankind.

The Emergence of Mankind

The question of human origins has intrigued every generation. Charles Darwin himself added a biological dimension with the publication of *The origin of species* in 1859. The controversy aroused by Darwin centred very largely around the mistaken idea that the theory of evolution implied that humans were descendants of the apes. This mistake is still encountered with surprising frequency, even though Darwin's original work and the many studies conducted since then all make the evolutionary proposition quite clear: humans are not descended from the apes, the two branches evolved simultaneously from a common ancestor which existed sometime in the past.

Among evolutionists, the question of human origins is basically a question of when the divergence of the ape and human lines occurred, and what the common ancestor looked like. For the greater part of the time since Darwin's day it has been assumed that the answers to these questions would be supplied by the fossil remains of the ancestral forms which might be recovered from geological deposits of ever-greater antiquity—if only those fossils could be found. Thus began the search for the missing link, as it became popularly known. By the 1960s the results of these fossil hunts had provided the basis for a widely-accepted scenario in which humans had evolved from *Ramapithecus* on a line which had split from the apes some 30 million years ago. Since the 1960s, however, this fossil-based scenario has been displaced by one based on biochemistry which puts the human/ape split at just 5 million years ago.

Modern DNA Evidence

Instead of studying fossil bones, biochemists have used the genetic material (DNA—deoxyribonucleic acid) of related living species to measure the amount of time which has passed since they diverged from a common ancestor. This work is based on three findings: first, DNA accumulates random mutations and changes over time which are evident in the protein structure of all individuals of a species. Second, as two lineages diverge from a common ancestor, each lineage accumulates changes in its DNA which are different from those of the other. Third, the accumulation of changes tends to occur at a regular, almost clocklike rate through time. Clearly, the greater the differences, the longer the divergence, and biochemists have thus been able to put a timescale on the divergence of the apes and humans. The orang-utan split away from the African hominoid stock about 12 million years ago, and the gorilla lineage diverged from the common ancestor of apes and humans about 8 million years ago. The chimpanzee and human lineages were the most recent to diverge from the common ancestor, their split having occurred about 5 million years ago.

Origin of the Hominid Lineage

In one sense the facts of human origins can be reduced to a series of dates at which humans and related species diverged from their common ancestors. But an intriguing question remains even then: what caused the splits; why did the species diverge from their common ancestor?

A species is the result of reproductive isolation. If the individual members of a viable breeding population reproduce only among themselves for any length of time, the genetic changes which accumulate with each generation will eventually produce a closely-related population which is significantly different from both its ancestral stock and the other descendants of that stock. If the process continues long enough a discrete species will have evolved, one which can only produce fertile offspring among its own kind. It can be supposed with some certainty that the reasons for the isolation which provoked speciation lay in the prevailing ecological circumstances of the time. Food supply would have been a primary factor, and this would have been susceptible to other factors such as climatic variation, the incursion of competing animals, climatic changes, or simply the pressures of a growing population.

Divergence of Gorillas and Chimpanzees

Any one or a combination of these ecological factors could have moved a viable breeding population of individuals into reproduction isolation where they might evolve into a discrete species. Migration is the most obvious course by which such isolation could have been achieved—but not the only one. Exploiting an alternative food resource, or adopting different social strategies could have achieved a similar degree of isolation even in close proximity with the ancestral population.

Precisely why the gorilla, chimpanzee and human lineages diverged between 8 million and 5 million years ago is not known. It may have been a consequence of the major climatic fluctuations which occurred during that time, when the overall pattern ranged from hot and dry to wet and very cold. The tropical forests retreated to the equatorial region, woodlands became dominant and grasslands proliferated. And with the changes in vegetation the composition of resident animal populations changed too. Many species became extinct, particularly among the browsers, while the grazers became more numerous. Doubtless the common ancestor of apes and humans was also affected by these developments, but the only certainties are that divergence and speciation occurred during that time, and that the distinctive characteristics of the living species can be considered as adaptations which proved advantageous to a reproductively isolated population.

Distinctive Human Characteristics

The distinctive characteristics of humans are the adaptation to a terrestrial way of life and bipedal locomotion; the much reduced face and jaws, and the greatly enlarged brain. In evolutionary terms, bipedalism was the crucial development, and it has been suggested that this was a consequence of the climatic changes which reduced the forest area and thereby increased competition for its resources. Under pressure from other arboreal primates, the human ancestor found a niche on the savannah. Whatever the case, bipedalism offered extensive evolutionary advantages. This was not because bipedalism itself is a particularly effective means of locomotion but rather because it freed forelimbs from locomotor functions and made them available for other purposes. One of the most important of these was the use of tools, and subsequently toolmaking. When the ancestral hominids first colonised the terrestrial habitat they had few inbuilt defence mechanisms and the ability to use stones, sticks and bones to ward off predators must have been of considerable survival value (as has been observed among present-day chimpanzees when they take to the ground). Initially used for defence, tools eventually were used in attack, heralding the adoption of a hunting mode of life. Toolmaking is also thought to have been one of the practices which favoured the development of language, and, since toolmaking called for fine manipulative skills, hand and brain evolved together; particularly those parts of the brain concerned with precise motor control and tactile sensation.

Advantages of Bipedalism

Another consequence of freeing the forelimbs through bipedalism was that carrying became so much easier. Thus food and other items could be carried over considerable distances and this facilitated the establishment of a home base. Perhaps even more important, the human infant could be carried in its mother's arms and held close to her body, allowing a much closer and more intimate relationship between mother and child than is possible in other animals. In terms of its physical development, the human infant is born in a very immature state; in part because of the limitations to the size of the birth canal imposed by the demands of bipedalism, but especially because of the large brain size of adult humans. It is therefore long dependent on parental care. This raises problems in a society where pregnant women and nursing mothers become dependent upon the group for food. Social bonds were forged in response, and it has been argued that the evolution of the particular form of reproductive cycle found in humans, in which the female is receptive to the male throughout most of her menstrual cycle should be seen as a means of ensuring that a male will be willing to assume responsibility for females and offspring.

FOSSIL EVIDENCE OF HUMAN EVOLUTION

A fundamental premise of palaeoanthropology (the study of man in times past) rests on the contention that unequivocal evidence of human evolution would be found in fossils of known antiquity linking modern man to extinct ancestor. Ideally, the fossils should comprise a series of complete skeletons from a precisely dated sequence of time: this would enable scientists to trace the evolutionary development of humans with complete certainty. But the arbitrary nature of the fossilization process virtually eliminates all chance that such an ideal could ever be achieved or even approached. Far from ideal, palaeoanthropology has had to work with a slowly accumulating collection of diverse and often very fragmentary specimens ever since it became an established discipline in the mid-19th century. In the first fifty years only five specimens were discovered; another twenty-five years passed before a dozen were known, and even today the significant specimens could all be accommodated on a billiard table.

The fossils have come from Europe, the Far East and Africa; they span over 3 million years, but as clues to the process of human evolution during that time they represent a minute fraction of mankind's potential ancestry. It has been calculated that ten skulls from East Turkana in Kenya (an exceptional collection covering 1 million years), for example, represent only one individual in every 100 million.

Problems of Evidence

The shortage of evidence is compounded by other problems. Uncertainties concerning age, for instance, mean that differing features which may represent evolutionary change over time cannot be placed in chronological order. And many fossils are so broken, distorted or incomplete that unequivocal interpretation of their significance is rarely possible. In such cases, different authorities may emphasize the importance of different features with equal validity, and the points distinguishing their interpretations may be so slight that each depends as much upon the proponent's beliefs about the course of human evolution as upon the evidence presented.

Discoveries, including fossils and a trail of fossilized footprints, have, however, shown that hominids were fully bipedal more than 3·6 million years ago, though the configuration of skull and jaw remained distinctly apelike for some time thereafter, while brainsize did not begin to approach modern proportions until 1·5 million years ago.

Finding the Fossils

Fossils (from the latin *fossilis*, meaning dug up) are the end products of a process in which organisms are buried and infiltrated by minerals which replace them, molecule by molecule, until, where organic material existed before, stone remains, exactly preserving the form of the original. Fossils have been the source of virtually all that is known about the evolution of life—from the oldest known forms (microscopic fossil algae dating back to 3·5 billion years) to modern times.

For an organism to become fossilized it must first of all be entrapped in a suitable material, away from the attention of scavengers and decomposers. Aquatic organisms comprise by far the greatest number of fossils, not only because they have been more numerous throughout the history of life, but also because the seabed or lake bottom favours fossilization. Terrestrial organisms are less commonly found as fossils (most are consumed or decomposed by other creatures soon after death), and hominid fossils are among the rarest of all.

Palaeoanthropologists wishing to find the fossil remains of early humans are limited by two major factors. First, humans evolved in the comparatively recent past and were not numerous until recent times—which means that the total number available for fossilization must always have been relatively small. Second, their way of life and the terrain they occupied were unlikely to favour the fossilization of their remains, and there are few places in the world where fossil beds of a suitable age and composition are exposed.

Early European Sites

In scouring the world for potential fossil deposits, palaeoanthropologists have found ancient caves to be a most productive source of fossils (and not only of hominids). Whether originally used as shelters, or as dens to which predators such as leopards or hyenas may have retreated with their victims, bones left in the cave did not decay, but were fossilized as debris and rockfalls filled the caves. The first hominid fossils ever known to science were discovered at cave sites in Europe—Cannstadt in Germany (*c.*1700); Koestritz, Upper Saxony (1820); Kent's Cavern, Devon (1829); Engis in Belgium (1833), Gibraltar (before 1848), Neanderthal in Germany (1857). Several of the discoveries made before Darwin published his theory of evolution in 1859 received little notice at the time of discovery; some were lost. Investigations moved to the Far East at the end of the 19th century, where *Homo erectus* was recovered from riverbed deposits in Java (1891), and again in cave deposits near Peking (Beijing) during the 1920s.

Fossil Discoveries in Africa: The Olduvai Gorge

Cave sites in South Africa have also proved to be a good source of hominid fossils. Alerted in the 1920s by quarrymen exploiting the lime-rich infills of ancient cave systems in the dolomitic hills, palaeoanthropologists have since recovered a number of important fossils from these sites.

The famed fossil sites of East Africa are predominantly volcanic in origin; the ash settling from eruptions associated with the formation of the Rift Valley having created conditions that were particularly suitable for the fossilization of bone. At Olduvai Gorge in Tanzania, where an ancient lake basin was inundated by successive eruptions of ash and subsequently drained by geological faulting, a river has sliced through the deposits to reveal much evidence of the hominids who frequented the area from at least 2 million years ago. Volcanic eruptions similarly preserved the 3·6 million year old footprint trail at Laetoli, near Olduvai.

As at Olduvai, volcanic activity and a lakeside environment were also responsible for the preservation of hominid fossils dating from 3·1 million years ago which have been found in the Afar depression of Ethiopia, and those dating from 1·8 million years ago found in the Koobi Fora region of the Lake Turkana basin, northern Kenya. *See also* **T53(2)**

Assessing the Age of Hominid Fossils

The age of a fossil is of paramount importance to the palaeoanthropologist in the assessment of its evolutionary significance. Until the late 1950s scientists could do no more than assess the age of their finds in *relative* terms, that is according to the kinds of other fossil animals found in the same deposit or sequence of deposits. The fossil record as a whole gives a broad picture of the order in which various animal forms have evolved and become extinct through the course of geological time. Hominid fossils are not found among the remains of dinosaurs, for instance, so must be younger; on the other hand, they must be older than any extinct animals (such as hyenas and pigs) which may be found in deposits overlaying the hominid beds.

Relative dating was always of limited use to palaeoanthropologists since human evolution occurred in a recent and extremely brief period of geological time (if the whole of Earth history was condensed into 24 hours, man would have existed for little more than one minute). Estimates of the fossils' age in years were made from time to time, but they were rough estimates based on guesses of how fast evolution proceeds, and of the rate at which sedimentary deposits accumulate. Most underestimated the actual ages which were given when developments during the 1950s, enabled geochronologists to give an *absolute* date for hominid fossil deposits.

Methods of Dating

Several methods of absolute dating have been applied to the study of fossil man:

Radiometric Dating is based on the principle that a radioactive "parent" element decays into a stable "daughter" element at a constant rate. Once the rate of declay is known, the age of a sample can be calculated from the ratio of parent to daughter elements which it contains. It should be noted that it is not the fossils themselves that are dated, but the deposits in which they are found. The cave sites of South Africa and elsewhere are devoid of materials suitable for radiometric dating, but the volcanic beds of East Africa have proved especially informative in this respect because they contain the minerals necessary for the *potassium-argon* dating method, which measures the ratio of the radioactive isotope of potassium, K-40, to its decay product, the gas argon 40. Potassium-argon is used for the absolute dating of deposits between 230,000 and 26 million years old, which makes it particularly suited to the needs of palaeoanthropologists.

Fission-Track Dating: a method in which the age of a specimen is assessed from the tracks made by the fission of uranium atoms within them. The density and number of tracks already present in the specimen are compared with those produced when the specimen is exposed to neutron radiation in the laboratory. This comparison provides the basis for an estimate of age.

Radiocarbon Dating: the radioisotope carbon-14 accumulates in living tissue, but begins to decay after death. The rate of decay is known, and so the proportion of carbon-14 remaining in a specimen is a measure of the time which has passed since the organism ceased to live. After about 50,000 years, however, so little carbon-14 remains that dating becomes impossible. This limited timespan makes the methods of little use to palaeoanthropologists, but it has proved immensely useful to archaeologists in the dating of wood and other organic materials.

Thermoluminescence: with the passage of time, certain substances accumulate energy in the form of electrons trapped at defects in the crystal lattice of their constituent minerals. When the materials are heated this energy is given off as a "puff " of light (thermoluminescence, or TL); the intensity of that light is a measure of how long the energy had been accumulating in the material, and this can be set against a known timescale to give an estimate of the material's age. The method has been particularly useful in dating archaeological finds such as pottery, where it is certain that the firing process reset the material's TL clock to zero when the pot was made, but it has also been used to date flints that were dropped in early man's campfires. These go back to 100,000 years ago.

Geomagnetic Dating (also known as **palaeomagnetic dating**): makes use of the fact that the Earth's magnetic field has changed direction many times in its history. When metals are deposited in sediments they align with the prevailing magnetic field, which is then effectively "fossilized" as the sediments harden. The record of these directional changes through geological time establishes a sequence of broad time-segments which can be used for dating deposits directly, or as a check of other methods.

THE FOSSIL LINEAGE

From the earliest days of palaeoanthropological research, investigators have tended to consider the fossils in chronological order (on either the relative or the absolute timescale), from oldest to youngest, and to describe the differences between them as progressive evolutionary changes which have led, ultimately, to modern man. So long as the number of hominid fossils remained small, and the temporal distance between them large, this attractively simple scheme remained valid, inculcating a general readiness to believe that human evolution had been a straightforward single-line affair, unwaveringly directed towards its ultimate expression: *Homo sapiens sapiens* and contentious only in the matter of which human attributes were acquired first—restructuring of the jaw, the bipedal gait, or the large brain?

A Single-Line Sequence?

Straightforward and attractive, yes, but contradicting the evidence of evolution in many other mammalian lineages. The fossil remains of pigs, horses, and antelopes, for example, display a tremendous amount of variation, not only through the geological sequence, but also at any given point on it, indicating that their evolution had been more of a radiation than a single line, with extinctions and proliferations of species occurring at many points in their evolutionary histories. Indeed, the frequency of extinction and speciation found in the fossil record of most organisms whose remains have been found suggests that such patterns are the rule. Why should humans be the exception?

The answer emerging from the tremendous advances made in palaeoanthropological research over the past half century is that they are not. Though the total number of fossil hominids is small (as was the total number of hominids available to be fossilized, especially when compared with the size of living pig, antelope and horse populations), it shows that there have been extinctions and speciations during the course of human evolution too.

The fossil hominids discovered so far date from over 5·5 million years ago to less than 30,000.

The Australopithecines: The Oldest Hominids

Discoveries in Ethiopia and Kenya have suggested that earlier theories may have underestimated the age of our earliest ancestors by as much as two million years. The lineages of these new specimens are, however, not universally accepted. Notwithstanding this, the group called the *Australopithecines* represent the oldest group of hominids, dating from 3·7 to 1·6 million years ago. Most authorities now accept four species—*Australopithecus afarensis*, *A. africanus* (or *gracile*), *A. boisei* and *A. robustus*.

The Work of the Leakey Family

In 1959 Louis Leakey (1903–72) and his wife, Mary (1913–96), recovered an almost complete skull, lacking the mandible, from deposits at Olduvai Gorge in Tanzania subsequently dated at 1·7 million years by the potassium-argon method.

After 1969 teams under the direction of National Museums of Kenya Director, Richard Leakey (1944–), recovered numerous australopithecine fossils with both gracile and robust affinities from 1·4 to 1·8 million year old deposits at East Turkana, northern Kenya. In 1985, the same team recovered a robust australopithecine skull from 2·5 million year old deposits on the west shore of Lake Turkana.

Between 1973 and 1977 joint French and American expeditions recovered large numbers of gracile australopithecine fossils from deposits dated at 2·6 to 3·3 million years ago in the Afar depression region of north-eastern Ethiopia. The fossils proved to be remarkably similar to others found at Laetoli, near Olduvai Gorge, by Mary Leakey in 1974–5 which were dated at 3·6 million years.

The fossil hominids discovered at Laetoli came from the same age deposit as a trail of fossilised footprints, and this circumstantial evidence invites the inference that the trail was made by those same hominids—*A. afarensis*. Evidence has been adduced for and against, but the issue remains contentious.

HOMO HABILIS

The taxon was created by Louis Leakey and his co-authors in their 1964 *Nature* paper describing hominid remains excavated at Olduvai Gorge in 1961 from deposits dated at 1·7 million years by the potassium-argon method. The fossils comprised a lower mandible, skull fragments, and a group of handbones. They were found in association with stone tools, and this was a persuasive factor in the authors' decision to assign the fossils to the genus *Homo*, since no tools had ever been found incontrovertibly associated with the australopithecines and it was generally considered that man by definition was a toolmaker. Hence the name, *Homo habilis*, colloquially translated as "handy man".

More Discoveries at Olduvai

Further remains of *Homo habilis* were found at Olduvai in succeeding years, including teeth, limb bones and a badly crushed and distorted skull. Richard Leakey's team at East Turkana discovered the skull known as 1470 (from its museum accession number KNM-ER 1470), which is informally described as *Homo habilis*, as are sundry other finds from East Turkana. Remains assigned to *Homo habilis* have also been recovered from excavations at the Swartkrans and Sterkfontein cave sites in South Africa, and at deposits in the Omo river basin in southern Ethiopia. In 1986, a new survey of the Olduvai Gorge deposits (led by Donald Johanson), recovered numerous fragments of skull, jaw and limb representing a single individual, which was subsequently assigned to *Homo habilis*.

The fossil evidence of *Homo habilis* recovered to date gives the species wide distribution through Africa, and a timespan dating from 2·1 to 1·8 million years ago. The species' mean brainsize is estimated to have been 750 cc.

The Status of Homo Habilis

The status of *Homo habilis* itself has not been very much clarified in the decades since it was first described. Two main issues have arisen: First, the discovery of *Homo erectus* fossils from 1•6 million year deposits at East Turkana indicates that *Homo habilis* was one of at least three hominid species alive at that time (the other was *A. robustus*), which questions its status as an ancestor of *H. erectus*. Second, the *Homo habilis* fossils discovered at Olduvai in 1986 by Johanson and his team show a considerable degree of affinity with the *Australopithecus afarensis* material dating from more than 3·5 million years ago, which suggests that the ancestral form remained unchanged for a very long time, and that the *Homo* characteristics evident in later specimens of *H. habilis* must have evolved very quickly.

HOMO ERECTUS

The most widespread and longest-surviving of the fossil hominids. Remains have been found in north and east Africa, Europe, Indonesia and China. The fossils date from 1·6 million years ago (West Turkana) to less than 300,000 years (China). Mean brain size ranges from 900 cc in early specimens to 1100 cc in late specimens.

Java Man

The first known specimens were described by Eugene Dubois (1858–1940) in 1894 and included a calotte (the cranial vault) and a complete femur (thighbone) excavated from sedimentary deposits comprising freshwater sandstones, conglomerates and volcanic material at a bend of the Solo river in Central Java, Indonesia. The cranial capacity was relatively small (900 cc) while the femur was entirely human, and this combination led Dubois to assign the fossils to a new species: *Pithecanthropus erectus*, meaning erect ape-man, while the specimen became popularly known as Java Man. When fossils of similar configuration were found in China (Peking Man) both the Java and Peking material was assigned to the taxon *Homo* with sub-specific distinctions made for the Java (*Homo erectus javensis*) and Peking material (*Homo erectus pekinensis*). Subsequently, sub-specific distinctions were dropped and the taxon became known as *Homo erectus*.

Remains displaying *Homo erectus* characteristics have been recovered in Europe from sites in Germany, Hungary, Greece, and France, and in 1960 a skull found at Olduvai Gorge extended the range of the species to Africa. Subsequently, further remains were found in Morocco and Algeria, in the Omo river basin of Ethiopia, and the Lake Turkana basin, northern Kenya.

The Turkana Boy

In 1985 a virtually complete *Homo erectus* skeleton was found in deposits on the western side of Lake Turkana dated at 1.6 million years old. The remarkable preservation of the specimen is thought to be the result of the body having sunk quickly into lake silts after death. The skeleton is immature, its development matching that of a modern 12 year old. Estimates based on its limb size and modern growth rates suggest that the individual would have stood 1·68 m tall as an adult. Cranial capacity is as yet undetermined, but clearly relatively low. The forehead is low and recedes, as does the chin.

The Affinities of Homo Erectus

Though *Homo erectus* is well positioned in time to be both a descendent of earlier hominid forms and an ancestor of modern humans, several questions arise from its distribution and physical characteristics. Some authorities argue that the Asian and African forms are so distinct that the latter should not be assigned to *Homo erectus*. Others have suggested that the species represents a side branch of human evolution which became extinct, and its co-existence with *Homo habilis* at East Turkana indeed could be seen as reason for dismissing it from the human line.

There is also continuing debate on whether the relatively incomplete material from Europe represents the "true" *Homo erectus* or a group that should be more closely aligned to modern humans. This in turn raises the question of the *Homo erectus/Homo sapiens* transition: was this a gradual change, as some authorities see demonstrated in the Omo material? Or was there a long period of stasis followed by abrupt change?

HOMO ANTECESSOR (PIONEER MAN)

A species identified from a jaw bone and teeth found in the Atapuerca hills near Burgos in Spain and dating back to between 1·2 and 1·1 million years ago.

'East Anglia Man', whose settlements at Pakefield, Suffolk, and Happisburgh, Norfolk, are the oldest ancient human sites yet found in Britain, was probably identical to, or closely related to, *homo antecessor*. The Pakefield site dates back some 700,000 years, but Happisburgh, uncovered in 2010, dates back between 780,000 and 990,000 years and is the earliest human settlement yet found in Northern Europe. More than 70 flint tools and chips have been recovered from Happisburgh, but no human remains, so the identification of 'East Anglia Man' with *homo antecessor*, although highly likely, cannot be proved. He would have arrived in Britain over the land bridge which then linked it with mainland Europe, across what are now the Straits of Dover, to settle in Happisburgh at the mouth of the large river which later shifted its course southwards to become the modern Thames. The rigours of the subsequent Ice Ages would have forced 'East Anglia Man' to migrate back southwards or die out. *Homo antecessor* is not thought to have been a direct ancestor of modern man, *homo sapiens*.

HEIDELBERG MAN

An archaic human whose remains were found in 1907 and who is likely to have been the ancestor of both modern man, *homo sapiens*, and also of 'Neanderthal Man'. 'Heidelberg Man' was characterised by large brow ridges, sloping forehead, and a heavy chinless jaw, and lived between 524,000 and 478,000 years ago.

'Boxgrove Man', whose remains were found at

Boxgrove, near Chichester, West Sussex, in the 1990s, and at some 500,000 years old are the earliest actual human remains yet found in Britain, appears to have been related to 'Heidelberg Man'.

ARCHAIC HOMO SAPIENS

A term applied to specimens which might be said to exemplify the *Homo erectus/Homo sapiens* transition mentioned above, and also integral to the proposition that modern man evolved in Africa in the relatively recent past. The definitive specimen (Rhodesia Man) was discovered in the course of mining operations at Kabwe, Zambia in 1921, and comprises a complete cranium, teeth and skeletal fragments. Recent appraisal of the site and associated finds has suggested that the remains date from at least 125,000 years ago. Cranial capacity is 1280 cc, indicating an enlarged brain.

Numerous specimens assigned to the group have come from more than 30 sites spanning Africa from north to south and covering a timespan ranging from 500,000 to 30,000 years ago. Some display features characteristic of the ancestral hominids, others are entirely modern. An age of about 100,000 years has been given to comparable forms known from Qafzeh in Israel, but all other evidence of anatomically modern man known from outside Africa is significantly younger.

This is seen as indicating that modern man originated in Africa and migrated from there to populate the rest of the world not more than 200,000 years ago.

NEANDERTHAL MAN

The first specimen was discovered by quarrymen clearing a cave in the Neander valley, near Dusseldorf in 1857. Following its classification as a distinct species in 1864, *Homo neanderthalensis* soon became symbolic of a misguided view of early man as an inferior and degenerate version of modern man. Based at first on a shortage of evidence and a determination to believe in the purity of the human line, this misconception was later reinforced by the distinguished palaeontologist Marcellin Boule (1861–1942) in a series of reports on Neanderthal remains found in cave sites at La Chapelle-aux-Saints and La Ferrassie between 1908–1912. Boule interpreted skeletal deformities as indicative of an habitual slouching gait and concluded that Neanderthal Man was every bit as degenerate as had been popularly supposed. Subsequent studies have shown that the deformities were the result of arthritis and that the Neanderthals were a sturdy and successful race, well-adapted to the environmental conditions of their time.

Features of Neanderthal Man

Discoveries of Neanderthal fossils at Engis in Belgium (1832), and Gibraltar (before 1848) predated the original find, and many more remains have been found in Europe, Iraq and Israel. Bone structure and stout muscular attachments indicate that the Neanderthals were generally short and thick-set, with large feet and hands and a body form similar to that of modern cold-adapted people.

Average brain size was over 1400 cc (some 10 percent larger than modern human, relative to body size) and exceeded 1700 cc in some large males. Dating of the fossil sites indicates that the Neanderthals lived from about 130,000 to 35,000 years ago.

Thus they appear to have been a well- adapted and successful group of hunters and gatherers who ranged across Europe with the advance and retreat of the Ice Age.

Indeed it is now thought 'Neanderthal Man' was a positive evolutionary response to the need imposed on man by the Ice Ages to hunt at close quarters, which put a premium on strength rather than on agility. Our old perceptions are changing.

The Affinities of Homo Neanderthalensis

Anatomical characteristics evident in both the Neanderthals and *Homo erectus* indicate that the two shared a common ancestry and possibly even a direct line of descent, but their relationship to modern man is far less clear. There are common characteristics, but much more that is different between the two forms. Moreover, it is generally felt that the proximity of the dates at which the Neanderthals disappeared and the modern humans became prevalent leave little time for evolution to have effected the change from one to the other (but all humans today have some Neanderthal DNA).

After 100,000 years of unchallenged existence, Neanderthals disappeared around 35,000 years ago. Only the remains of people anatomically indistinguishable from modern humans have been recovered from more recent sites. They probably became extinct in Western Europe, possibly Belgium, having lived alongside Homo sapiens for *c.* 20,000 years.

'Neanderthal Man' walked as upright as modern man. He could use fire in a controlled manner and he buried his dead and cared for the sick and elderly. He developed the production of jewellery, possibly, under the influence of modern humans. He etched primitive cave art. Feathers were used as body adornment. Recent evidence suggests they may have used an early form of language.

HOMO SAPIENS SAPIENS

Fossil remains of anatomically modern humans are known from sites in Europe, Africa, the Near East, Asia and Australia. The first and most famous to be found was Cro-Magnon Man, unearthed in the Dordogne region of France in 1868 and dating from about 40,000 years ago. Fragmentary fossils of a wholly modern form recovered from a cave at the Klasie's river mouth in South Africa date back to more than 100,000 years ago, while those from the Mungo site in Australia are from 32,000 years ago. On present knowledge, these two finds represent the greatest time-depth and geographic dispersal of early modern humans.

The dispersal of modern humans appears to have been rapid between 30,000 and 20,000 and became especially so with the domestication of animals and crop plants from about 10,000 years ago. Migration into the Americas was delayed until a landbridge across the Bering Straits opened through glacial ice *c.* 18,000 years ago, but excavations have shown that modern humans were well-established in north America soon thereafter and had spread as far south as the Chilean Andes by 12,000 years ago.

The spread and proliferation of anatomically modern humans is inextricably linked with the development of technological skills, art, and circumstantial evidence of social interaction. While the Neanderthals employed a stone tool technology little improved from earlier forms, the anatomically modern humans introduced the flint-flaking techniques by which a greater variety of tools were made. Personal adornment and careful burial of the dead were features of their lifestyle not so evident among the Neanderthals, and cave paintings speak eloquently of their perceptive talents.

More recent studies of mitochondrial DNA, which is inherited strictly through the maternal line because the sperm does not contribute mitochondria to the fertilised egg cell, show that modern humans can trace their ancestry to a single female, commonly referred to as Eve, a member of a population living in Africa some 150,000 years ago.

POSTSCRIPT: HOMO NALEDI

New members of the human family tree continue to be discovered. A new species *Homo naledi* was discovered in 2013. It had been found in a barely-accessible cave in South Africa near Johannesburg. Around 2,000 specimens have been found, from 12 bodies, of a species that lived *c.* 2 million years ago. It was uniquely adapted both to walk and also climb trees.

VI. SCIENTIFIC TABLES

TABLE OF ELEMENTS†

Element (Symbol)	Atomic Number	Atomic Weight	Valency

* In the cases of these elements, which have been artificially prepared, atomic weight in the chemical sense is meaningless; the integral mass of the most stable isotope known is given

Note: In 1961 the isotope of carbon-12 replaced oxygen as a standard, the weight of its atom being taken as 12. This change has meant a slight adjustment in atomic weights from the old chemical scale

† Those elements with atomic numbers above 103 are called **transactinides**. Although the table below lists those transactinides whose existence is confirmed, their names (and some of their properties) are sometimes only provisional. All elements with an atomic number greater than uranium are termed **transuranics**.

No	Element
104	unnilquadium (rutherfordium)
105	unnilpentium (hahnium)
106	unnilhexium (seaborgium)
107	unnilseptium (bohrium)
108	unniloctium (hassium)
109	unnilennium (meitnerium)
110	ununnilium (darmstadtium)
111	unununium (roentgenium)
112	ununbium (copernicium)
113	ununtrium (nihonium)
114	ununquadium
115	ununpentium (moscovium)
116	ununhexium (tennessine)
117	ununseptium (oganesson)
118	ununoctium

Roman type—metals
Italic type—semiconductors
Bold type—non-metals

These designations refer to the normal materials usually at room temperature. Processes like heating or compressing can turn metals into insulators and vice versa.

Note: It is possible by artificial methods such as bombardment by other nuclei to produce elements with atomic numbers greater than 103. However the very heavy elements tend to be unstable and decay spontaneously into lighter elements. Because the lifetime of such elements is short no element with an atomic number greater than Uranium (92) occurs naturally on earth. *See footnote*, **T56**. In 2016, elements 113, 115, 117 and 118 were officially added to the periodic table by the International Union of Pure and Applied Chemistry.

MEASURES, UNITS AND METROLOGY

Introduction

Before any quantity can be measured one must decide on the *units* used for measurement. For example, a 2 lb loaf of bread when weighed in ounces will give 32, *i.e.* 2 × 16. This is because there are 16 oz in a pound. It would be incorrect to say the weight of the loaf is 2 or 32. We say it is 2 lb or 32 oz and we can convert from one unit to another by knowing the ratio of their sizes.

If a standard pound is kept somewhere this can be used to calibrate other standard weights using accurate scales. These in turn can be used to calibrate other weights which in turn can be compared with the loaf with scales in order to weigh the bread.

The International Prototype Kilogram

Nowadays, for scientific purposes, weights are compared with that of the *international prototype kilogram*, kept at Sèvres in France. For a long time the length of an object was obtained by making a comparison, direct or indirect, with the standard metre if using the metric system or the standard yard if using the Imperial system. The standard metre was the length between two notches on a metal rod, kept at a controlled temperature, at Sèvres. Time is measured in seconds, which at one time was defined as a certain fraction of the tropical year.

The Problem of Definition

Definitions of this kind are unsatisfactory for two reasons. First, the tropical year is not constant and even the most carefully kept metal rods are liable to change their dimensions over a long period of time. Secondly, it is not always convenient to do a comparison with an object kept in France. Nowadays every effort is made to define units in terms of some fundamental property of matter which is reproducible everywhere and does not require comparison with one particular object. The second is now defined using an atomic clock and can be measured to an accuracy of 1 part in 10^{12}. Variations in the rotation of the earth are far greater than this. The metre is nowadays defined in terms of the distance light travels in one second. Although the kilogram could likewise be defined in terms of some fundamental quantity of matter, such as insisting the mass of an electron is 9.1083×10^{-31} kilogram, this quantity is only known to about 2 parts in 10^5. Comparisons with the standard kilogram can lead to an accuracy of the order 10^{-9}, so at present this definition of the kilogram stands.

The SI System

The scientist nowadays mainly uses the SI system of units. SI is short for "Système International d'Unités" and it is a system of metric units which has come into international use through the agency of such bodies as the General Conference of the International Bureau of Weights and Measures and the International Organisation for Standardisation (ISO) in whose work Britain participates.

Definitions of the Base Units

The system uses the *base quantities* listed below:

Quantity	*Name of unit*	*Symbol of unit*
Length	metre	m
Mass	kilogram	kg
Time	second	s
Electric current	ampere	A
Thermodynamic temperature	kelvin	K
Luminous intensity	candela	cd
Amount of substance	mole	mol

The seven SI base units are defined as follows:

The **metre** is the length travelled by light in a vacuum in 1/299 792 458 sec. (*See* **Metre, Section L**).

The **kilogram** is the mass of the international prototype of the kilogram (*q.v.*). Scientists use the word 'mass' where the layman would say "weight". Strictly speaking, weight is not a base quantity and is a measure of *force*.

The **second** is the duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the caesium-133 atom (*See* **Clock, Section L**).

TABLE I

Quantity	*Name of SI unit*	*Symbol*	*SI unit in terms of base units or derived units*
frequency	hertz	Hz	1 Hz = 1 s^{-1}
volume	stere	st	1 st = 1 m^3
density	kilogram per cubic metre		kg m^{-3}
velocity	metre per second		m s^{-1}
force	newton	N	1 N = 1 kg m s^{-2}
pressure, stress	pascal	Pa	1 Pa = 1 N m^{-2}
viscosity (dynamic)	pascal second		Pa s
work, energy, quantity of heat	joule	J	1 J = 1 N m
power	watt	W	1 W = 1 J s^{-1}
quantity of electricity	coulomb	C	1 C = 1 A s
electric potential, EMF	volt	V	1 V = 1 W A^{-1}
electric field	volt per metre		V m^{-1}
electric capacitance	farad	F	1 F = 1 C V^{-1}
electric resistance	ohm	Ω	1 Ω = 1 V A^{-1}
electric conductance	siemens	S	1 S = 1 Ω^{-1}
magnetic flux	weber	Wb	1 Wb = 1 V s
magnetic flux density	tesla	T	1 T = 1 Wb m^{-2}
inductance	henry	H	1 H = 1 V s A^{-1}
magnetic field	ampère per metre		A m^{-1}
luminous flux	lumen	lm	1 lm = 1 cd sr
luminance	candela per square metre		cd m^{-2}
illuminance	lux	lx	1 lx = 1 lm m^{-2}
heat flux density, irradiance	watt per square metre		W m^{-2}
heat capacity	joule per kelvin		J K^{-1}
specific heat capacity	joule per kelvin per kilogram		J kg^{-1} K^{-1}
thermal conductivity	watt per metre per kelvin		W m^{-1} K^{-1}

The **ampère** is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular cross-section, and placed 1 metre apart in vacuum, would produce between these conductors a force equal to 2×10^{-7} newton per metre of length.

The **kelvin**, unit of thermodynamic temperature, is 1/273·16 of the thermodynamic temperature of the triple point of water (*See* **Absolute Temperature, Section L**).

The **candela** is the luminous intensity, in the perpendicular direction, of a surface of 1/600 000 square metre of a black body at the temperature of freezing plantinum under a pressure of 101 325 newtons per square metre. Luminous intensity is a property of a *source* and is the amount of luminous flux (light) it throws out per steradian.

The **mole** is the amount of substance of a system which contains as many elementary entities as there are atoms in 0·012 kilogram of carbon 12. Since this number is approximately $6{\cdot}022\,17 \times 10^{23}$ a mole of hydrogen molecules, for example, is approximately this number of hydrogen molecules.

In addition to the base units, two SI *supplementary units* are listed below:

Quantity	Name of unit	Symbol of unit
Plane angle	radian	rad
Solid angle	steradian	sr

They are defined as follows:

The **radian** is the plane angle between two radii of a circle which cut off on the circumference an arc equal in length to the radius.

The **steradian** is the solid angle which, having its vertex in the centre of a sphere, cuts off an area of the surface of the sphere equal to that of a square with sides of length equal to the radius of the sphere.

Derived Units

Most quantities that occur in nature are *derived quantities* and are measured in *derived units*. Speed is a derived quantity which can be measured in metres/sec, so that the units of speed involve the definition of two base units, *i.e.* metres and seconds. It is said that speed has the dimensions of [length]/[time], also written $[L][T]^{-1}$, since the metre is a measure of length and the second is a measure of time. In any equation in science the dimensions of both sides must always be the same and this is often a useful check of whether the equation is correct. If a mile = 1609·3 metre and an hour = 3600 sec, one mile/hr = 1609·3/3600 m s^{-1}. Conversions between any unit and any other unit which measures the same quantity can be similarly obtained.

Table I (**T58**) gives a list of some important derived quantities that occur in nature and in the fourth column the SI unit that is used to measure it. Some of these derived units have a name (usually that of a famous scientist) and a symbol which are given in the second and third columns. Thus for example, the SI unit of force is a kilogram metre sec^{-2}, but this unit is also given the name of a newton. A force of 5 kg m s^{-2} is 5 newton, which can be written "5N".

Multiples and Fractions of Units

Within the SI system there are special prefixes for forming multiples and sub-multiples of its units.

Factor by which the unit is multiplied	*Prefix*	*Symbol*
10^{24}	yotta	Y
10^{21}	zeta	Z
10^{18}	exa	E
10^{15}	peta	P
10^{12}	tera	T
10^{9}	giga	G
10^{6}	mega	M
10^{3}	kilo	k
10^{2}	hecto	h
10	deca	da
10^{-1}	deci	d
10^{-2}	centi	c
10^{-3}	milli	m
10^{-6}	micro	m
10^{-9}	nano	n
10^{-12}	pico	p
10^{-15}	femto	f
10^{-18}	atto	a
10^{-21}	zepto	z
10^{-24}	yocto	y

Examples

Examples: one thousandth of a metre is one millimetre (1 mm); one million volts is one megavolt

Time

	second	*minute*	*hour*	*solar day*	*year*
1 second	= 1	$1{\cdot}667 \times 10^{-2}$	$2{\cdot}778 \times 10^{-4}$	$1{\cdot}157 \times 10^{-5}$	$3{\cdot}169 \times 10^{-8}$
1 minute	= 60	1	$1{\cdot}667 \times 10^{-2}$	$6{\cdot}944 \times 10^{-4}$	$1{\cdot}901 \times 10^{-6}$
1 hour	= 3600	60	1	$4{\cdot}167 \times 10^{-2}$	$1{\cdot}141 \times 10^{4}$
1 solar day	= 86400	1440	24	1	$2{\cdot}738 \times 10^{-3}$
1 year	= $3{\cdot}156 \times 10^{7}$	525,900	8766	365·24	1

Force

	newton	*dyne*	*poundal*	*kg force*	*pound force*
1 newton	= 1	10^{5}	7·233	0·1020	0·2248
1 dyne	= 10^{-5}	1	$7{\cdot}233 \times 10^{-5}$	$1{\cdot}020 \times 10^{-6}$	$2{\cdot}248 \times 10^{-6}$
1 poundal	= 0·1383	13830	1	0·01410	0·03108
1 kg force	= 9·807	980700	70·93	1	2·205
1lb force	= 4·448	$4{\cdot}448 \times 10^{5}$	32·17	0·4536	1

Energy, Work, Heat

	joule	*kW. hr*	*ft lb*	*calory*	*B.t.u*
1 joule	= 1	$2{\cdot}778 \times 10^{-7}$	0·7376	0·2389	$9{\cdot}478 \times 10^{4}$
1 kW. hr	= $3{\cdot}600 \times 10^{6}$	1	$2{\cdot}655 \times 10^{6}$	$8{\cdot}598 \times 10^{5}$	3412
1ft lb	= 1·356	$3{\cdot}766 \times 10^{-7}$	1	0·3238	$1{\cdot}285 \times 10^{-3}$
1 calory	= 4·187	$1{\cdot}163 \times 10^{6}$	3·088	1	$3{\cdot}968 \times 10^{-3}$
1 B.t.u.	= 1055	$2{\cdot}931 \times 10^{-4}$	778·2	252	1

1 kW. hr (kilowatt hour) is 1 unit as measured by the electricity meter.

1 B.t.u. is a British thermal unit and is the amount of heat required to raise the temperature of 1 lb of water by 1° Fahrenheit.

1 Therm is 100 000 B.t.u. and is equivalent to the heat generated by 29·3 units of electricity.

1 calorie is the heat required to raise the temperature of 1 gm of water by 1° C. The calorie as used by weightwatchers is actually 1000 calories as defined above.

1 erg is 10^{-7} joule.

1 electron volt (eV) is $1{\cdot}6 \times 10^{-19}$ joule.

Angle

	degree	*minute*	*second*	*radian*	*revolution*
1 degree	= 1	60	3600	$1{\cdot}745 \times 10^{-2}$	$2{\cdot}778 \times 10^{-3}$
1 minute	= $1{\cdot}667 \times 10^{-2}$	1	60	$2{\cdot}909 \times 10^{-4}$	$4{\cdot}630 \times 10^{-5}$
1 second	= $2{\cdot}778 \times 10^{-4}$	$1{\cdot}667 \times 10^{-2}$	1	$4{\cdot}848 \times 10^{-6}$	$7{\cdot}716 \times 10^{7}$
1 radian	= 57·30	3438	$2{\cdot}063 \times 10^{5}$	1	0·1592
1 revolution	= 360	$2{\cdot}16 \times 10^{4}$	$1{\cdot}296 \times 10^{6}$	6·283	1

1 rt angle = 90° 1 grade = 0·01 rt angle

Pressure

	pascal	*millibar*	*atmosphere*	*torr*	*lb/sq in*
1 pascal	= 1	0·01	$9{\cdot}869 \times 10^{-6}$	$7{\cdot}501 \times 10^{-3}$	$1{\cdot}450 \times 10^{-4}$
1 millibar	= 100	1	$9{\cdot}869 \times 10^{-4}$	0·7501	0·01450
1 atmosphere	= 101 300	1013	1	760	14·7
1 torr	= 133·3	1·333	$1{\cdot}316 \times 10^{-3}$	1	0·01934
1 lb/sq in	= 6895	68·95	0·06805	51·72	1

1 pascal = 1 newton/sq metre = 10 dyne/sq cm
1 torr is the pressure due to 1 mm of mercury.
By atmosphere is meant "standard atmosphere" which is 760 mm or 29·92 inches of mercury.

(1 MV). These prefixes are *recommended* but other multiples and sub-multiples will be used when convenient, *e.g.*, the centimetre (cm), the cubic decimetre (dm^3).

The following is a selection of points to note:

- (i) The name litre now means 1 cubic decimetre or 10^{-3}m^3 and is a measure of volume.
- (ii) Days, hours, and minutes are still used to measure time, though some scientists may prefer to use kiloseconds, *etc.*
- (iii) The SI unit of plane angle is the radian (rad), but degrees, minutes and seconds are still used as well. $1° = \frac{\pi}{180}$ rad.; 1 rad = 57·295 78° = 57° 7′ 44·81″
- (iv) A Celsius temperature, say 15 degrees, is written 15°C; note that 15C would mean 15 coulombs.

The Imperial System of Units (*see* **L2**)

Temperature

The Celsius scale is the same as the Centigrade scale. To convert from degrees Fahrenheit (°F) to degrees Celsius (°C), subtract 32 from the temperature in Fahrenheit and multiply by 5/9. To convert from Celsius to Fahrenheit multiply the temperature in Celsius by 9/5 and add 32. Applying this rule we obtain:

0° C = 32° F
5° C = 41° F
10° C = 50° F
15° C = 59° F
20° C = 68° F
25° C = 77° F
30° C = 86° F
35° C = 95° F

37° C (normal body temperature) is 98·6 ° F.

The absolute zero temperature (lowest possible temperature) is −273·15° C.

To convert from ° C to degrees Kelvin (° K) add 273·15 to the temperature in Celsius so that the absolute zero is 0° K.

To obtain the temperature according to the Rankine scale add 459·69 to the temperature in Fahrenheit. 0° Rankine is the absolute zero.

PLANET EARTH

This section examines the complex structure of the Earth as well as its early history and the origin and development of life. A Special Topic looks at the challenge of global climate change and progress at the 2015 Paris Conference. For further information on other planets of the Solar System and beyond, see Section T.

PLANET EARTH

THE EARTH'S STRUCTURE

The Earth is the third of the planets in the Solar System, orbiting the Sun at a distance of approximately 150 million kilometers. The Earth has the shape of a slightly flattened sphere, with an equatorial radius of 6378 km and a polar radius of 6357. It has a mass of $5{\cdot}97 \times 10^{24}$ kilograms, a density of about 5·5 grams per cubic centimeter, and an average surface gravitational acceleration of 9·8 meters per second per second.

The Earth is an almost spherical body with an equatorial radius of 6378km, and slightly less along its polar axis (due to the flattening of the poles). Seismic investigations have shown that the Earth is made up of three layers which are distinguished one from another by their composition and density. The central *core* of the planet is the densest of the three; the surrounding *mantle* is a thick shell of less dense rocky material, and above the mantle lies the thinnest, least dense and outermost layer, the *crust*.

The Core

At the centre of the Earth lies the core, a dense mass of iron and nickel with a radius of 3486 km. As there is no way to sample the core, its composition and properties are inferred from seismic studies, astronomical data (the way the Earth interacts with other bodies is affected by the density structure of the planet), and meteorites. (Iron meteorites, which are composed of a mixture of iron and nickel, are thought to come from the cores of asteroids that were smashed apart in collisions with other asteroids.)

The core is divided into two layers. The outer core, which extends to a depth of 5144 km, is liquid. It is thought that the convection of this metallic liquid creates the Earth's magnetic field. Although the inner core is hotter than the outer core, it is under more pressure and is therefore solid. It is a distinct region and the structure of the iron nickel alloy crystals there is different.

Scientists have now discovered that the Earth's inner core is rotating faster than the rest of the planet. No one is certain of the temperature at the centre of the Earth. It may be 4000°C–5000°C, or could be as high as 8000°C.

The Mantle

The thick shell of rocky material which surrounds the core. No one has sampled the mantle directly. Knowledge of its composition and structure comes from a number of sources. Volcanoes occasionally erupt pieces of mantle known as mantle xenoliths, which are primarily composed of dense iron and magnesium-rich (*mafic*) minerals such as olivine and pyroxene. Experiments that simulate the high pressures and temperatures in the mantle have given us a better idea of what minerals can exist there. Geochemical studies of igneous rocks such as basalt, which are thought to be derived directly from the mantle, are also of use in calculating its composition. Seismic studies have given us a view into the physical properties. The velocity of energy waves (seismic waves) traveling through the Earth after an earthquake or explosion depends on the properties of the rock (*e.g.*, density) they are traveling through. Using an array of seismometers recording seismic waves arriving at many different points on the surface, geophysicists can "image" the structure of the crust, mantle, and core.

The mantle is believed to be ultramafic in composition throughout, although the exact mineral assemblage changes with depth as pressure and temperature increase. In addition, there are probably slight differences in composition between the upper and lower sections of the mantle. In places (*e.g.*, below some volcanoes), the mantle is partially molten, but in general, although it is extremely hot, it is solid.

The Crust

The rocky outer shell of the Earth on which all known organisms live and the oceans lie is known as the crust. There are two fundamentally different types of crust: *continental crust*, which makes up the continents; and *oceanic crust*, which underlies the oceans. Continental crust is composed of a wide array of rock types, and has an average composition of that of a granitic rock, with an overall density of about 2·5 g/cc. Continental crust is on average 35 km thick, but is quite thin under some low plains and valleys, and as thick as 70 km under high mountain ranges. Oceanic crust, on the other hand, is composed primarily of the volcanic rock basalt overlain by sediments, and has an average density of about 3 g/cc. It covers 60% of the Earth's surface, but is much thinner than continental crust, on average 7 km. Overall, the crust is relatively cool and brittle, but its properties change with depth. Pressure increases by 300 atmospheres per km, and temperature increases by 25°C/km near the surface.

Plate Tectonics

Perhaps the most fascinating long-term change the surface of the Earth undergoes is that of *plate tectonics*. Plate tectonics is the theory that ascribes the large-scale structures of the Earth's crust (*e.g.*, mountain ranges, rift valleys, continents, and ocean basins) to the interaction of brittle pieces, or *plates*, of crust and upper mantle as they move about on ductile mantle below.

Most evidence of plate tectonics can be found at plate boundaries (or former plate boundaries), where plates are moving against one another. There are three kinds of active plate boundaries: *divergent margins*, where plates are moving apart; *convergent margins*, where plates are moving towards one another; and *transform margins*, where plates are sliding past each other. Each kind of margin is characterized by distinct topography and a particular type of seismic and volcanic activity.

The Mechanism of Plate Tectonics

The mechanism that drives plate tectonics has been a problem since continental drift was first expounded by Alfred Wegener in 1912. The prevailing theory is that the plates are riding around on convection currents in the mantle. Although the mantle is solid, it is extremely hot and under enormous pressures. Over long periods of time, it acts as a fluid. Its behaviour is somewhat analogous to pitch, which shatters when hit quickly with a hammer, but will flow under the force of gravity if left to sit for a while. The convection of the mantle is driven by temperature differences. Hot, buoyant material near the core rises, while cooler, denser material near the surface descends. It is thought that there are a number of large-scale convection cells in the mantle, which drive the plates in different directions above. The heat that drives convection comes from the decay of radioactive elements, and from the heat left over from the Earth's accretion 4.56 billion years ago. There are still many unanswered questions as to the precise nature of mantle convection and exactly how it translates into plate movement.

The Composition of the Earth's Crust

The many different kinds of *rock* found in the Earth's crust are each an assemblage of one or more minerals. A mineral, in its turn, is a discrete solid substance consisting of chemical elements, with a specific chemical composition and a characteristic crystal structure. Iron, for instance, is an element (Fe); iron oxide is a mineral (Fe_3O_4); iron ore is a rock composed of iron and other minerals.

Over 3700 minerals have been identified, but of these about 20 make up more than 95 per cent of the Earth's crust. And of the elements, 12 comprise 99·23 per cent of the total crust mass. Thus the crust consists of a limited number of minerals in which one or more of the 12 abundant elements is an ingredient. Oxygen is the most abundant element, comprising 45·20 per cent by weight of the crust, followed by silicon (27·20 per cent), aluminium (8·00 per cent) and iron (5·80 per cent).

The Rocks

The rocks of which the Earth's crust is composed, though numerous in their different mineral composition, can be grouped in just three families, distinguished one from the other by the manner in which they were formed.

(i) **Igneous rocks** (from the Latin *ignis*, fire). Igneous rocks are those which were formed from the cooling and solidification of *lava*, the molten rock which erupts from volcanoes. Basalt is the most common igneous rock, comprising about 80 per cent of all lava erupted by volcanoes.

(ii) **Sedimentary rocks**. Those rocks which are formed by the settling and consolidation of materials that had previously existed in some other form. Most originated as loose particles that were eroded from their parent material and transported in suspension by wind, water or ice to some other location, where they were deposited and subsequently consolidated into sedimentary rock – sandstone is a typical example, shale is another. Others were originally organic material, which as it died and decomposed formed beds of sedimentary rock.

Limestone, for example, was originally the shells and remains of marine animals; coal is a combustible sedimentary rock, more than 50 per cent of which is decomposed plant matter.

(iii) **Metamorphic rocks**. From the Greek *meta* (meaning change, and *morphe*, meaning form: thus, change of form) are those rocks which have been changed from their original form (either igneous or sedimentary) into something else by the effects of temperature, pressure, or both. The process is analogous to that which occurs when a clay pot is fired in the kiln. The high temperatures trigger a series of chemical reactions in the tiny mineral grains that make up the clay. New compounds form, and the soft malleable clay becomes hard and rigid. Marble is a metamorphic rock, transformed by heat and pressure from the irregularities of sedimentary limestone into a glistening mass of uniformly sized, interlocking grains of soft calcite.

The Rock Cycle

Geologists often refer to the *rock cycle*, the continuous alterations of rocks from one type to another. An igneous rock is broken down by weather and gravity; its pieces accumulate elsewhere as a sediment, the sediment is buried and lithified to form a sedimentary rock; the sedimentary rock is buried further and subject to tremendous heat and pressure; new minerals grow and a metamorphic rock forms; part of the metamorphic rock melts; the molten rock solidifies to form a new igneous rock.

The importance of rocks to earth science is not simply that they give us an indication of the composition of the Earth, but that they are windows into the past. Each type of rock forms in a particular environment. For instance, limestone forms in warm shallow seas, salt in hot deserts, and granite deep underground. Thus the presence of limestone indicates that the area was once a shallow sea, salt that it was once a desert, and granite that thousands of meters of rocks have eroded away to expose the rock below. James Hutton, the founder of modern geology, refered to rocks as "God's books," which tell the story of the Earth.

Minerals

Rocks are solid, naturally-occurring pieces of a planet. Most rocks are composed of one or more minerals (coal is composed of organic material, but it is still considered to be a rock). A mineral is a naturally-occurring, generally inorganic material with a specific chemical composition and a definite crystalline structure (its molecules are arranged in an orderly, repeating pattern). Although water is natural and has a specific composition, it is not a mineral because it is liquid and therefore not crystalline; water-ice, however, is a mineral because it has a crystalline structure.

Groups of Minerals

More than 3500 minerals have been discovered so far, but only about 100 are common in the crust. There are a number of groups of minerals, including carbonates, sulfides, phosphates, and native elements, but the largest group by far is the silicates. Silicates are all composed of silicon-oxygen molecules combined with other elements. In fact, there is much more oxygen in the Earth's crust than there is in the atmosphere.

Continents and Oceans

If the surface of the Earth were level, the sea would cover the entire planet. So why are there continents and oceans? One reason is buoyancy. The continental crust and oceanic crust are fundamentally different. The continental crust is thick and relatively light, while the oceanic crust is thin and dense. As a result, the continental crust floats high on the mantle in the same way that a huge, empty ocean liner floats high in the water, whereas the oceanic crust acts more like an overloaded barge.

The state of gravitational equilibrium of the crust is known as *isostasy*, and the flexing of the crust in response to loads imposed or removed from it is known as *isostatic adjustment*. Just as ships and icebergs have a submarine keel that keeps them in balance, so does thick continental crust. The Himalayas, for example, rise almost 9 km above sea level, but *descend* more than 60 km below sea level. It is also this isostatic adjustment that allows rocks that form at depths of many kilometres to buoy up as the rocks above them erode away.

EARTH HISTORY

Age and Origin of the Earth

The current theory of planet formation states that the Sun and planets accreted from a rotating cloud of dust and gas that contracted under the force of gravity about 4·56 billion years ago. Most of the material went in to making the Sun, while the remaining dust and gas accumulated to form rocks, then small bodies known as *planetesimals*, and finally planets. Because of the reworking of rocks on Earth, there are most likely no pieces left of the primitive Earth. The oldest rock dated so far is a 3·96 billion-year-old gneiss from Canada, while the oldest mineral grain is a 4·2 billion-year-old zircon grain from Australia. The 4·56 billion-year-old age of the earth is inferred from the ages of primitive meteorites, which are thought to be relics of the early solar system.

The Timescale

Earth's history is thus long, at least 4,560 million years. This stretch of time is virtually impossible to visualise but an analogy may make it more comprehensible. Imagine that Earth time has been but a single 24 hour day. If the Earth came into being at time zero, 0:00:00, then bombardment by meteorites would have lasted until 3am; there would not have been enough stability for the origin of life until 4am: 5:36am would see the first fossils and traces of bacteria. It would be well past noon before single celled algae appeared and seaweeds not until 20:28pm: 20 minutes later there were jelly fish; trilobites dominated the sea floor by 21:04pm. Plants reached the land by 21:52pm and coal swamps flourished by 22:24pm. Then, 32 minutes later the dinosaurs dominated, to be replaced by mammals at 23:39pm. Not until a minute to midnight did Humans come on the scene.

How Palaeontologists Date Fossils

How can Palaeontologists (geologists that study past life) have any idea about relative dates? Each layer of sedimentary rock contains vital clues to the environment in which that sediment was laid down. This is based on one of the fundamental principles of Geology, that the present is the key to the past, that by studying the sediments in today's environment, one can conclude that the same sediments lithified (cemented into rock) and would have been deposited under similar conditions in the past.

Sedimentary rocks also hold clues to the life forms of the time through the fossils that they contain; some rocks such as a coral limestone will be rich in fossils since coral reefs support a wide variety of creatures; the harsh conditions of a hot desert are not conducive to life. Rocks can be dated by radioactive isotopes so, putting all this evidence together, it is possible to reconstruct the *palaeoenvironment* (past environment) and the community (assemblage) of species that was then living in it. Molecular biology has made dating proteins another possibility.

However, the fossil record does not contain all creatures that have ever lived for, to be preserved as a fossil, an organism must have hard parts such as bone or shell. Only in rare circumstances can jellyfish or bacteria be preserved if the sediments were fine and burial very quick, perhaps by a submarine mudslide, so that currents or waves had no chance to stir up the delicate remains.

Main Geological Eras

The table set out later is a history of life on Earth, a time chart summarising the main stages in Earth's history. There are four major chunks of time called Eras, based on the differences in animal groups present in each one: Azoic (no life), Palaeozoic (ancient animals), Mesozoic (middle animals) and Caenozoic (recent animals). The earliest times are conventionally shown at the bottom, in line with another fundamental principle, the Law of Superposition which states that in an undisturbed sequence, a layer of rock will be younger than the ones below it and older than those above it.

Hand in hand with this law is the Law of Fossil Succession, that plants and animals that have parts hard enough to survive burial and compaction change through time and that where there are the same kinds of fossils and assemblages (groups of species together) in rocks of different locations, then they are of the same age. As exploration and technology, such as the scanning electron microscope, advance so the scope for reading the rocks increases, interpretations change and what is written here becomes out of date.

THE DEVELOPMENT OF LIFE

The development of life on Earth has been neither smooth nor gradual. There have been times of abundance balanced by times of major extinctions, of which there have been at least five. Long periods of gradual evolution are punctuated by brief periods of rapid change, either in proliferation, as the explosion of life forms in the Cambrian seas, or in extinction, as the virtual disappearance of the dinosaurs some 70 million years ago whch has so captured the popular imagination and occupied many palaeontologists in debate as to its cause. Changes in palaeogeography, as the continents have shifted positions relative to each other, have prompted radiation or extinction, migration and mixing.

The Origin of Life

How did life originate? The answer can probably only ever be conjectural. It is commonly thought that complex organic molecules, amino acids, synthesized naturally in Precambrian oceans. These basic ingredients of proteins would have had favourable environments of high energy from both the sun (no ozone layer to screen out UV rays) and warm water from volcanic hydrothermal vents. The earliest known fossils are those of prokaryotic cells (small with no nuclei) in the anaerobic (without oxygen) oceans. By 1000 million years ago (mya) eukaryote cells (large, membrane bounded nuclei containing chromosomes) were well established. Here was an opportunity for evolution, since these cells reproduced sexually allowing genetic material to mix and mutate.

To have life means having the ability to reproduce; reproduction requires the passing on of genetic information. This is done on Earth today by the very complex protein substance, DNA (deoxyribonucleic acid). (*see* **Nucleic acid, T47**)

Gradually microbes became more complex and colonial, by 3000 mya creating layered structures called *stromatolites*; these still form today at places such as Hamlyn Pool in Western Australia.

Proterozoic Era Discoveries

The late Proterozoic has been an empty mystery but modern finds are constantly filling in this gap. For example, Ediacara chert from Australia has revealed flat bodied creatures only 0.1mm in size, 610 to 510 million years old. Alongside these are fossils that look like feathery fronds up to a metre long. Others are pouchlike with no recognisable circulatory or nervous system; it is thought that their air-mattress appearance was due to fluid-filled hydraulic support. These have now been discovered in rocks world wide, but were they a life form that failed or the ancestors of modern species? Amongst these fossils have been found trails and holes left by metazoans; it seems that these had been burrowing in sediments since 1000 mya.

What seems certain is that early bacteria developed in the absence of oxygen; the blue-green algae (cyanobacteria) released this vital gas into the oceans and atmosphere, setting the stage for Biology's Big Bang.

The Early Cambrian Period

In the early Cambrian period the world recovered from a severe glaciation (nicknamed Snowball Earth) and shallow seas flooded the continents. (There was an extraordinary radiation of life forms; almost every major group of animals appeared then, 540–500 mya. Indeed, so rapid was this radiation, current research puts it at only 10–20 million years, that it suggests another kind of evolution in very short time periods in addition to the more steady Darwinian one.

The cause of this dramatic explosion is a matter of geological conjecture. Had the cyanobacteria established so much oxygen that more complex life was possible? Was it that so many new species created more diverse food chains such that there was increasing competition in the predator and prey relationship so adaptation was necessary for survival?

The Cambrian Explosion

The Cambrian explosion of life produced important marine creatures such as brachiopods (bivalved marine animals whose valves are not identical) and trilobites (rather like woodlice in appearance, bodies in three sections), with eyes as well developed as any modern insect, in abundance.

Significantly, these creatures had made an advance by developing shells. These gave support for muscles and protection against new predators, something that pre-Cambrian Ediacara species would not have needed.

Astonishingly, every design for a body plan that has ever existed (there are eight main ones) came into being then, and no new ones have appeared since though many minor ones became extinct in the first major extinction recorded in the rocks at the end of the Cambrian Period.

This extinction after such diversity indicates that maybe extinctions do not need a major external cause such as Ice Ages or asteroids after all; perhaps a small evolutionary step creates an advantage to one species that upsets the balance of a whole ecosystem.

The Appearance of Fish

Fish first appear in the fossil record in the Ordovician. Their soft bodies were armoured by external skeletons. By Silurian times, a group of fish emerged with internal skeletons and body armour reduced to scales. By late Devonian times, 370 mya, there were lobe finned fishes that had stout bony supporting appendages, unlike the ray finned fishes (such as trout or salmon of today) that have much thinner bone structures arranged as a fan in their fins. Some of these lobe fins had one upper and two lower bones similar to those of tetrapods (four jointed legged, land living vertebrates); indeed, the first tetrapods evolved in the Devonian, about 360 mya and were the forerunners of amphibians.

The Evolution of Plants

If animals were to occupy the land surface, then plants must have got there first or else there would have been no food source to sustain them. Early plants evolved in water, using currents for reproduction, but in the Silurian, or even earlier than that, there was greening of the land with a skin of cyanobacteria. Once plants developed the capacity to live on land, with spores with walls and stems and leaves with cuticles that would prevent drying out, stomata to control gas exchange, vascular system to circulate water and tough polymers such

TABLE: GEOLOGICAL TIME SCALE

	ERA	AGE (MYA, million years ago)	CHARACTERISTICS
CAINOZOIC	QUATERNARY		Modern humans
		2	
	TERTIARY		Mammals & flowering plants diversify. Earliest hominids.
		65	
MESOZOIC	CRETACEOUS		Dinosaurs included in major extinction. Flowering plants common.
		145	
	JURASSIC		Early birds & mammals. Dinosaurs abundant.
		205	
	TRIASSIC		First dinosaurs & mammals. Coniferous trees common.
		250	
PALAEOZOIC	PERMIAN		Mass extinction of many marine species, including trilobites.
		290	
	CARBONIFEROUS		First winged insects. Large primitive trees. First reptiles.
		360	
	DEVONIAN		First seed-bearing plants (ammonoids). Early tetrapods. First amphibians and insects.
		410	
	SILURIAN		First jawed fish, first upright plant.
		440	
	ORDOVICIAN		First land plants and early fish. First jawless vertebrates.
		500	
	CAMBRIAN		Trilobites dominant. First molluscs.
		570	
PRECAMBRIAN	PROTEROZOIC		First invertebrates & multi-celled/ soft-bodied organisms.
		2,500	
	ARCHÆAN		Bacteria/single celled organisms.
		3,800	Oldest known fossils.
	ORIGIN OF EARTH	4,560?	

as lignin to prevent collapse, then invasion was possible. Mosses and liverworts were probably the first: these have different combinations of land requirements, but not all of them.

Developments in the Devonian Era

The oldest known vascular land plant is Cooksonia found in Silurian rocks in Wales and Ireland, only a few millimetres long; by the Devonian they were several centimetres. Other Devonian plants reached 8 metres in height; Carboniferous ones were even taller, the clubmoss Lepidodendron was 50 metres or more and the horsetail, Calamites, was 20 metres. These forests decayed into the coal deposits found today from Pennsylvania to Poland. They contain fossils of insects with 50cm wing spans rather like giant dragonflies. Gymnosperms, seed bearing plants, first arose in the Devonian; they include seed ferns and the most successful conifers that first carried their cones in the Carboniferous forests.

Early Cretaceous was brightened by the first Angiosperms, flowering plants where the ovule is protected, not naked as in the gymnosperms. They have been successful; their almost identical descendants dominate today's plant life.

The Development of Amphibians

The development of amphibians had marked a significant step towards animal life colonising land. They appeared in two major groups, frogs and toads in the Triassic and newts and salamanders in the Jurassic. To move out from water, amphibians had to solve several problems, impermeable skin, air breathing lungs instead of gills, and skeletal support, especially a rib cage to hold up the internal organs—bodies are not weightless on land as they are in water. However, they could not spread far onto land, needing swampy conditions for their eggs. The first recorded reptile was found in Carboniferous tree trunks where it had gone in quest of insects. Reptilian success stems from laying eggs that could keep themselves wet, with amniotic fluid enclosed in a shell. By the Permian, when hot, dry conditions did not favour amphibians, reptiles on land spread wide and grew ever larger.

The Mesozoic Era: Age of the Dinosaur

The next era, the Mesozoic, is most distinguished in the popular imagination by the dinosaurs. There are two important branches in the structure of these reptiles, the Saurischians (lizard-hipped) and the Ornischians (bird-hipped). The saurischians had a pelvis with a pubic bone pointing forward and downwards; the group included the giant vegetarians such as Diplodocus and Brachiosaurus and the carnivorous (meat eating) hunters like Tyrannosaurus Rex and Allosaurus.

It has been accepted for more than a century now that birds are descendants of dinosaurs. The first specimen of the link between them, the famous Archaeopteryx, was discovered in Germany in 1861. The creature had a mouthful of teeth, claws on its wings, long bony tail but also something new in the fossil record, feathers. Archaeopteryx is very similar to dinosaurs of the bird-hipped group that includes the equally famous Velociraptors. There are constantly new fossil finds that help to "flesh out" the evolution of the birds. As tall plants produced layers of vegetation, gliding and then flight became a major way of life (a successful one; 70 % of all animal species alive today are insects).

The First Reptiles

Contemporary with the dinosaurs, and poised to assume their dominant role, were warm blooded mammals. The first reptiles with mammal-like features appeared in the Upper Carboniferous, but by Late Triassic, 210 mya, the first true mammals are found. Mammals have dispensed with the need to lay eggs outside of their bodies. There are two ways of doing this; the marsupials give birth to tiny, helpless young that must spend months in a pouch suckling milk. Today the marsupials have reached their greatest variety in Australia, isolated by the separation of continents and free from disturbance by placentals, until invasion by humans.

Placental mammals retain young in the womb for longer, nourished by blood through the placenta. The earliest placentals are Cretaceous but they could not diversify until dinosaurs were no longer competition. Then they rapidly radiated to reach twenty orders in the Palaeocene, the ancestors of all modern groups and others now extinct. These include carnivores, insectivores, rodents, ungulates (like pigs, camels, hippo and cattle) and primates. From these primates, first seen in the Cretaceous, emerged hominids. But that is a different story! (*see* **Human Evolution T48–55**).

THE MINERAL WORLD

Types of Minerals

Minerals are naturally occurring solid elements or combination of elements; very few elements occur simply on their own (copper, silver and gold are good examples of ones that do) so most minerals are compounds of ions bonded together with an atomic structure. For example, copper is frequently found bonded together with carbonate, $CuCO_3$, as the pretty green mineral malachite or in a brassy one called chalcopyrite where iron is included in the copper carbonate. The presence of some hydroxide in the chemical bonding will result in the glorious blues of azurite.

Chemical Composition of Common Minerals

Each specific chemical composition does not vary, no matter how small the fragments into which a piece may be broken, because that composition is a fixed ratio. Take quartz, one of the most common of all minerals; its chemical formula is SiO_2, which means that for every one silica atom there are two of oxygen. This one:two ratio is constant for all quartz. Each mineral, to a greater or lesser degree, forms crystals that have a distinctive geometry, such as cubes or prisms, whose faces follow the atomic structure of the molecules making up that mineral. A surprising example of how atomic structure affects a mineral's characteristics comes by comparison of graphite with diamond. Both are composed of carbon but in diamond, the carbon atoms are arranged in a cubic lattice, internally so strong that diamond is the hardest known mineral. In graphite, on the other hand, the carbon atoms are weakly bonded together in flat sheets so that it is soft with a greasy feel. The difference is a result of the position in which the carbon grew. Diamond's strength is a result of greater depth; it forms at the equivalent of 150 km or more deep in the Crust.

Constant Characteristics

Since the chemistry of each mineral does not vary, there is a distinctive set of constant characteristics by which each can be identified, such as colour, hardness, lustre, streak on an unglazed tile, form, cleavage (the preferred direction in which a mineral breaks) and density. A good textbook on minerals will describe fully these features but three common examples will illustrate the point. Calcite, quartz and halite are three common, normally colourless minerals which have a non-metallic lustre. Lustre is the way in which a mineral reflects light; it might be metallic, vitreous like glass, pearly, resinous or greasy, looking as if it were coated with oil. One of the first tests to do to tell them apart is hardness, the ability to withstand scratching, which is assessed using Moh's Scale of Hardness.

Hardness: The Moh Scale

Moh was an Austrian geologist who listed ten minerals from the softest, Talc, to the hardest known, Diamond, and assigned them values of 1 to 10 (1 is Talc, 2 Gypsum, 3 Calcite, 4 Fluorite, 5 Apatite, 6 Orthoclase, 7 Quartz, 8 Topaz, 9 Corundum, 10 Diamond). A finger nail is hardness 2·5 so anything that it can scratch will be softer than that; likewise, a steel blade is hardness 6·5 so anything that it will scratch is softer than it and anything that will scratch it is harder than steel. Calcite will scratch halite which has a hardness of 2.

In terms of crystal form all three are different, quartz having well formed six-sided prism shaped ones, calcite has rhombohedral and halite has perfect cubic ones. If the crystals are broken, then both halite and calcite will have perfect cleavage, meaning that they split in planes parallel to the crystal faces; quartz does not have any cleavage and broken faces will be rough or look like the curves of a shell.

Streak is not a significant test for these three, unlike haematite which, though it may look grey or brown, leaves a red streak on a tile. However, there are individual clues which readily distinguish the halite from the calcite (the crystal form and hardness leaves us in no doubt about quartz). In a clear and well formed piece of rhomboidal calcite, any image put under it will be double refracted (two images will be seen slightly overlapping). Also, all forms of calcite will fizz with dilute hydrochloric acid. Halite has one unique characteristic, its taste of salt.

Colours

Quartz has been described above and is the only one of the six that is not a whole family of minerals although it has several varieties, distinguished by colour, such as rose quartz which is pink and amethyst, purple. These beautiful colours are the result of trace impurities of atoms such as iron or titanium. In large masses, it can be milk white. Where quartz has precipitated from water, it is fine grained with chalcedony an important variety, called agate when it is decoratively colour banded and flint when it is grey and breaks with a conchoidal fracture resembling the growth rings of a shell.

Olivines are pale yellow-green magnesium iron silicates, with vitreous lustre and hardness of 6·5 to 7. The *Pyroxenes* are a diverse family ranging from dark green to black. *Amphiboles* are ferromagnesian silicates of which hornblende is the most common.

Feldspar, Mica and Calcite

Feldspars are a group of aluminium silicate minerals that account for 60% of all minerals in the Earth's crust, common in oceanic crust and, with quartz, comprising 75% by volume of the continents. The strange name is Swedish and means "field mineral", a reference to the frequency with which it needed clearing from farmland. Feldspar family minerals are not glassy like quartz but appear porcelainic and dull. There are two common types, either orthoclase which is red, pink or whitish, or plagioclase, green, dark grey or white in colour but *striated* (scratched in parallel grooves). When feldspars break, they do so along flat, rectangular faces.

Mica has black/shiny (biotite) and white/pearly (muscovite) forms. Both are distinctive because they can be peeled into thin, flat, transparent sheets.

Calcite is a carbonate, not a silicate, but, though of little significance in terms of the whole crust, it is common in sedimentary rocks at the surface.

Igneous Rock Granite

Igneous rock granite is a very good example to show how minerals form the building blocks of rocks since all the crystals, whether well- or partly-formed, are clearly visible to the naked eye. There are interlocking crystals of feldspar, mica and quartz; usually the feldspar has the best developed crystals because it was the first mineral to begin to crystallise out from the molten magma. Quartz forms at the lowest temperature and so it "fills in" between the pre-existing solids. Often minerals grow in restricted spaces and so perfect faces cannot form. Much more important to a geologist is the angle between the faces which will be constant, in the case of quartz, 60 degrees, no matter what the size of those faces.

Ore minerals have economic importance. Iron as an oxide, either Fe203 Haematite or Fe204 Magnetite, the only mineral that will swing a compass needle, and with sulphur as pyrite. Others include Bauxite (aluminium) *etc.*

SPECIAL TOPIC

GLOBAL CLIMATE CHANGE

Introduction.

For whatever reasons, there is little doubt that the weather in the UK is becoming more volatile and more extreme. The last few years have seen hotter summer spells, heavier winter snowstorms, massive floods and even tornadoes. Globally, 2016 was officially named the hottest since comparable records began in 1880. In the UK, the mildest and wettest December on record was accompanied by severe floods in Cumbia as well as Scotland. Our weather continues to become increasingly volatile and unpredictable.

It may be thought incongruous to describe climate change as a current environmental controversy. It is after all nothing new. The last Ice Age finally retreated from Britain perhaps only some 12,000 years ago, and the North African coastal plains, much of which are now desert, were the granary of the Roman Empire. What, though, is new is the speed of change and the risk it poses that eco-systems will be unable to adapt at the same rate. The fears of some members of the UN Intergovernmental Panel on Climate Change that southern Africa could face a 100-year drought, convey the scale of that risk.

Even if there is overall adaptation, localised impacts could still be severe. For example, any diversion of the Gulf Stream could give the United Kingdom a climate akin to that of Labrador.

The Impact of Climate Change.

Climatologists have long predicted that global warming would be accompanied by a marked increase in the frequency of extreme weather conditions, and that prediction was borne out in 2010 to a remarkable degree. At the end of July, a temperature of 37·7°C (100°F) was recorded in Moscow, the highest since records began 130 years previously. Even Siberia reached 37°C. The heat was accompanied by the worst drought in more than a century causing catastrophic forest fires across twelve of the country's regions. At the other extreme, southern Asia had its heaviest monsoons in years with 2·5 million people being made homeless by Pakistan's worst floods in 80 years, while temperatures in Buenos Aires, the capital of Argentina, fell to –1·5°C, the lowest ever recorded there.

Figures released by Munich Re, one of the world's largest reinsurance companies in August 2010, showed that the number of floods and landslides across the globe had trebled since 1980 and that the number of storms had doubled. The annual average number of disasters had increased from 339 in the 1980s to 693 between 2000 and 2009.

As one direct consequence, large tracts of low-lying land across the globe are rapidly becoming uninsurable with highly adverse consequences for countries, notably those in the Caribbean, parts of Asia and the Pacific, dependent on inward investment for tourism and other forms of economic development.

The Onset of High Temperatures.

The hottest years globally since records began in the 1860s have now occurred since 1990. The World Meteorological Organisation reported in December 2009 that the ten years from 2000 to 2009 were 0·44°C warmer than the annual average of 14°C between 1961 and 1990. Up to 2017, the ten warmest years in the UK since records began in 1910 have all been since 2000. Meanwhile, Europe and Asia both suffered from extreme temperatures in 2003, with southern France recording temperatures of over 40°C (104°F), some 5–7°C above average. Switzerland had its hottest June for 250 years.

Ironically, the River Elbe, the scene of catastrophic flooding in 2002, experienced such low water levels that navigation had to be suspended. In Britain in August, the London area broke the 100°F (37·9°C) barrier for the very first time.

In India, the pre-monsoon heatwave produced peak temperatures of 45°C, some 2–5°C above average. On the other hand, the USA suffered from 562 tornadoes in May, beating the previous monthly record of 392 in June 1992.

Although the temperature variations involved may appear modest in themselves, they need to be set against the estimate that the last Ice Age was provoked by average temperatures only 4–5°C lower than those with which we are familiar. The sensitivity of the human body to very small fluctuations in blood temperature may be a useful parallel.

The Phenomenon of Global Warming.

Climate change is a comprehensive term for the changes arising from the phenomenon of global warming generated by the build up of what are known as "greenhouse gases" in the atmosphere. The best known of those "greenhouse gases" is carbon dioxide (CO_2), and the first area of controversy, which is essentially scientific, is the actual rate of change and the extent to which it is man-made. The Intergovernmental Panel on Climate Change currently estimates that warming is occurring at a speed of between 1·4°C and 6·4°C every century, rates which may sound modest but which at the higher end of the scale could raise sea levels by up to one metre in the same period. Some scientists believe, however, in the light of the accelerated melting of the Antarctic ice sheet, that the sea level rise could be as much as 1·4 metres. The rate of ice loss from the Antarctic Peninsula rose from an estimated 25 billion to an estimated 60 billion tons a year between 1996 and 2006, which statistic may be compared with the 4 billion tons of drinking water supplied to British households every year.

Similarly, there is now almost unanimous acceptance that global warming is being accelerated by greenhouse gas emissions from the burning of fossil fuels, particularly coal and oil, with natural gas as a lesser but still major contributor.

Although most greenhouse gas emissions are produced by domestic households, industry, commerce and agriculture, road transport is responsible for 21% and that proportion is increasing. Improvements in the domestic and industrial sectors are steadily being outweighed by the increasing levels of use of cars and lorries. Even the substantial gains of 50% or more in fuel efficiency over the last 20 years have been outweighed by longer journeys and the preference for more powerful models. The net result has been that CO_2 emissions from road vehicles have increased by 70%–80% throughout the European Union alone in the last 20 years. The explosion in air transport is adding to the problem significantly.

The UK's Committee on Climate Change recommended back in 2009 that the contribution of road traffic to greenhouse gas emissions be reduced by the introduction of road pricing as an additional tax, with no reduction in fuel duty, and by rigorously enforcing a 60mph limit on motorways, which latter would save 2·9 million tonnes of CO_2 a year.

Rising Sea Levels and Flooding.

Rising sea levels are a daunting threat not only to countries like Bangladesh, where more than 100 million people live on land barely above sea level, but also to those extensive areas of north western Europe like East Anglia, the Netherlands and the German coastal plain where the land drainage of centuries past has caused the soil to dry out and shrink, putting much land significantly below the present sea level. A study published in November 2005 showed that global sea levels were rising twice as fast as they had been 150 years previously.

A particularly severe example of flooding was that of the catchment areas of the Danube and the Elbe back in 2002, which caused incalculable damage in Austria, the Czech Republic and eastern Germany. The historic cultural cities of Salzburg, Prague and Dresden were amongst the areas hardest hit.

The 1992 Rio Conference.

Such anxieties had been aired at the United Nations Conference on Environment and Development held in

Rio in 1992, and led to the drafting of the Convention on Climate Change. The European Union for its part had earlier agreed after much argument to stabilise CO_2 emissions at 1990 levels by the year 2000. The results of these initiatives, in themselves fairly undemanding, remain modest. The EU target was only narrowly met despite the substantial contribution made in some countries, notably the UK, by the substitution of natural gas for coal to generate electricity,

Carbon Taxation and Trading.

Greenhouse gas emissions are unlikely to be stabilised let alone reduced unless fuel use becomes more expensive, which in practice means taxation of energy generated from fossil fuel sources. Although such taxation has the potential to be popular as one facet of a movement away from taxing incomes and employment towards taxing resource consumption, which would help to reduce unemployment, it will be seen as a regressive additional burden unless it forms part of a comprehensive redistributive package. Moreover, it is feared by many in industry, particularly in fields such as chemicals where energy use is high, by governments such as those of Japan and the US which are apprehensive of the impact on their competitiveness, by developing countries who fear their development might be stifled, and by the oil producing countries who do not wish to see a reduction in the sales of what may be their sole significant export.

Taxation in some form is, however, almost certain to come because the challenge of climate change will not go away. Indeed, modest initiatives have been taken in the UK with the introduction of the Climate Change Levy (CCL), and in Germany.

Nevertheless, the currently preferred approach is "carbon trading" whereby every qualifying industrial installation is allocated an emissions allowance. Any installation which emits more than its allocated allowance must buy credits accordingly from one which has emitted less, thus establishing a market price for carbon emissions.

The European Union's own emissions trading scheme became operative on 1 January 2005, but it is widely agreed that the initial allocations were too high and that the resulting emissions trading price has been too low to affect behaviour significantly. The European Commission hopes that stricter allocations in the second phase of the scheme running from 2008 will remedy any such problems. The numerous compromises approved by the EU following the European Council of December 2008 must, however, put that hope in question.

The Kyoto Conference.

It is not surprising against this overall background that the third conference of the 150 parties to the Convention on Climate Change, held in Kyoto, Japan, in December 1997, was politically charged. The European Union, strongly supported by the Association of Small Island States, urged a target of a 15 per cent reduction in emissions of three key greenhouse gases by the year 2010 with Britain being ready to reduce its emissions by 20 per cent in any event. America and Canada were initially unwilling to envisage any reduction at all, although America expected China and India to commit themselves to future reductions. China and the G7 group of developing nations, on the other hand, called for reductions of 35 per cent by the wealthier countries by the year 2020.

A Limited Agreement.

It is perhaps remarkable in these circumstances that any agreement was reached at all, even if it was dubbed second-rate. A Protocol was nevertheless adopted stipulating a binding target of a 5·2 per cent average reduction by the major industrialised countries on 1990 levels of emissions of a "basket" of six greenhouse gases by the years 2008–12. The different regions would, however, receive differential treatment. The EU would make a reduction of 8 per cent as would most of the countries of central and eastern Europe, the United States one of 7 per cent, and Japan and Canada 6 per cent. New Zealand, Russia and the Ukraine would stabilise emissions at 1990 levels but Australia would be allowed an increase of 8 per cent. No emission reductions were required of the developing countries, but America did, however, gain acceptance of the controversial concept of "carbon trading" between developed and developing countries, which is on the one hand a politically realistic approach but on the other a disincentive to real domestic change—a case of do as I say, rather than do as I do. In 2001, however, President Bush took America's opposition to its logical conclusion by withdrawing from the whole Kyoto agreement.

The Failure of the Copenhagen Conference.

The UN had hoped that its long-planned international conference in Copenhagen in December 2009 would be able to negotiate a global agreement to succeed the Kyoto Protocol on its expiry in 2012. The European Union had already committed itself to a reducton of 20% in greenhouse gas emissions by 2020, compared with 1990 levels, in the belief that cuts of that magnitude by the world's major emitters would be sufficient to keep the rise in global temperatures to no more than 2°C above pre-industrial levels, the maximum increase with which the world is likely to be able to cope without the risk of serious damage. Adherence to the 2°C limit would then require a reduction by 50% on 1990 levels by 2050.

The hopes of the UN, the EU, and the world's environmentalists were, however, dashed when Brazil, China, India and the African states united to oppose the agreement of any binding international treaty. It is hard to fault the terse judgement of Jonathan Porritt, a former chairman of the UK Sustainable Development Commission: "To bill the Copenhagen accord as anything other than a failure is simply dishonest." Its essential content can be expressed very briefly. Most of the participating nations committed themselves to the general ambition of preventing global temperatures from rising by more than 2°C, but no nation or group of nations was required to make any specific cuts.

Furthermore, poorer nations were promised up to $30 billion to cope with climate change and a goal of $100 billion annually was set for 2020 for helping them to adapt to global warming and adopt clean technology. The source of all this funding was, however, not specified.

Not only was there no treaty, but the accord was not even endorsed by the countries participating, merely noted. Although the Copenhagen Conference was in itself a failure, there were differing views as to whether the outcome should be seen as merely a temporary setback or whether it should be interpreted rather as final notice that the concept of a meaningful international climate treaty was a mirage for the foreseeable future. For the optimists, the important thing was that a global deal was finally struck: for the pessimists the important thing was the emptiness of that deal and in particular the absence of any binding targets.

Doha and Lima.

At the UN Climate Change talks at Doha (in Qatar) in 2012 the poor countries at last received a pledge that they would receive funds from the richer nations for 'loss and damage' they had incurred. Although this was an important advance, the details were obscure and the pledge fell short of legal liability.

In December 2014, the 194 countries represented at the Lima Call for Climate Action made some progress (albeit painfully slow) to commit each country to draw up a national pledge to cut greenhouse gas emissions. It was hoped the 2015 UN summit in Paris would make further progress.

Commitments under Kyoto.

All EU nations were committed under the Kyoto Protocol to reducing their greenhouse gas emissions, which precludes a switch back to coal unless carbon storage can be made a practical proposition or emissions are reduced disproportionately in some other sector, most obviously transport. The UK,Germany and Poland are in any event the only EU member states which still generate a significant proportion of their electricity from coal. Natural gas has been consumed at a rate which can only be described as imprudent, and the EU now envisages that it will have to import 70% of its needs by 2020.

The demand for gas and oil by China continues to grow at an extraordinary rate, confirming forecasts by the International Energy Agency that the global demand for oil would increase by almost half over the next 25 years. China's own demand has doubled over the last 10 years, and it is now the world's second largest importer.

The Paris Summit.

Nearly 120 world leaders, and a total of around 40,000 delegates attended the Paris Summit from 30 November to 11 December 2015. Contrary to the expectations of sceptics the agreements reached exceeded expectations. The agreement commits all 195 signatories to a limit of below 2°C on global warming above pre-industrial levels. Countries will meet in 2018 to check on progress. However, the great minus factor of Paris was that so much remains voluntary there is no real enforcement; nothing is binding and after four years countries can opt out. Whether, as President Hollande of France declared, it is a "major leap for mankind" must remain open to debate.

Subsequent developments have left that debate wide open. On the positive side, the UK succeeded in reducing its emissions by a further 6% in 2016, having done slightly better than the EU average between 1990 and 2014. On the negative side, it has been estimated by government that much of the reduction of 42% on 1990 levels is attributable to the movement of production overseas and that once imports are included the UK's carbon footprint has fallen by only 6% since 1997, whereas emissions associated with imports from China have more than doubled over the same period.

Such considerations have been, however, overshadowed by President Trump's repeal in 2017 of US regulations to restrain carbon emissions. It set a malign precedent.

MEDICAL MATTERS

Here we give a brief summary of modern medical knowledge for a wide variety of the most common illnesses. The section also looks at many medical problems of contemporary society, from bowel cancer to the obesity epidemic and from the dementia timebomb to shingles and meningitis. Also included are such health threats as dengue fever and the return of rickets. However, it must not be allowed to replace your doctor, who should be consulted if you are at all worried. The main index at the end of *Pears* provides an easy reference guide.

MEDICAL MATTERS

PART I. INTRODUCTION.

TWENTY-FIRST CENTURY MEDICINE

The Medical Revolution.

Much in medicine which is now taken for granted (that for the majority of diseases caused by identifiable organisms there is a specific drug treatment, for example) was undreamed of even as recently as 60 years ago. Progress in diagnosis, in preventive medicine and in treatment, both medical and surgical, has been so rapid as to be almost breathtaking. A doctor retiring from active practice this year has seen smallpox completely eradicated, poliomyelitis practically banished globally, tuberculosis become curable, coronary artery disease relievable surgically and he or she will have witnessed the dramatic progress in the field of molecular biology and in the research by immunologists and geneticists into their efforts to control parasitic diseases like bilharzia, malaria and river blindness that affect millions of people in the Third World. One aspect of medicine and medical thinking still resistant to progress in understanding in spite of continued research is the effect of mind on body.

The Effect of Mind on Body.

Many of us still like to think that our bodies are just something we have got into, like cars, that ill-health is simply something that has "gone wrong" in one system or another and that therefore provided we find the appropriate expert (a chest physician, a gastro-enterologist or an ophthalmic surgeon, for example) to correct the fault, we will recover. Whereas that idea holds good for a broken leg, for instance, with many diseases the idea that mind can be totally separated from the "defective" part just isn't good enough. You cannot simply divorce your stomach, your bowels, your liver or your heart from your "self ". They are all part of you and react, as you yourself react, to all the stresses and anxieties, fears and worries that are part and parcel of modern living.

Stress and Anxiety.

Mens sana in corpore sano—a sound mind in a sound body. Your body and its many parts may be helped to normal function by modern medicines and surgery but, in general, it will only stay that way if you can rid yourself of all those emotional blemishes—anger, frustration, fear, worry and anxiety—which trouble you. Easier said than done, of course, but a good physician can help with good advice, with medicines if necessary—or simply with his ear. Emotional stress can not only inhibit healing of such things as duodenal or gastric ulcers but may even *cause* them.

There are many diseases now recognised which are known to be associated with excess stress factors if not actually caused by them. Mainly these are diseases of the digestive tract or of the heart and blood vessels and you will find some of them discussed in the appropriate sections. However, some stress in moderation is probably good for us.

The state of the mind has more influence on bodily functions than you might think and recovery from many serious conditions can be slowed or hastened, depending on your state of mind. Every doctor has had experience of the patient who "loses the will to live", a situation which is unfortunately commoner than the reverse.

Preventive Medicine.

A word about preventive medicine—or helping yourself to health. A great deal of nonsense has been talked about the healthy life; at one time we were told to take eighteen chews to each bite, to do deep breathing, to take plenty of exercise, to get lots of fresh air, to eat regularly (or to indulge in peculiar diets). But more recently eminent doctors have cast doubt on some of these fancies. Moderate exercise is indeed necessary to health, but athletes who indulge in violent exercise have not always been noted for longevity. Fresh air is pleasant and stimulating, but, where actual breathing is concerned, it is no better than the air in most rooms, though secondary smoking is now rightly considered extremely harmful. Certainly, one of the problems of our time is air pollution, but at present we are considering ordinary fresh air in comparison with the air indoors, and, in this case, the experts say there is little difference so far as health is concerned.

Diet.

A balanced diet containing correct amounts of the basic food substances is essential, but there is no evidence that when, or at what intervals, you eat makes the slightest difference—unless you are a sufferer from stomach ulcer, in which case it is necessary that the intervals between meals should not be too long. The whole business of having meals at fixed intervals is nothing but a social convention, and in modern life obviously a matter of convenience. However, there is evidence that it is unwise to eat a heavy meal near bedtime. The biggest challenge for many today is not to eat too much. As discussed later, obesity is becoming one of the great challenges of our time.

Sleep.

Sleep is certainly a necessity. But different people require different amounts of sleep. Some manage on as little as three hours, others need ten or more.

In a number of studies of men and women who lived to a ripe old age it was found that the only factors in common between them were that they had a good balanced diet of healthy food, that they had contented minds, and that they were interested in something which gave them an aim in life. They also came of long-lived families—for living a long and healthy life depends partly upon heredity. This factor we cannot alter!

Key Rules of Health.

(1) Don't abuse your body –*i.e.*, exercise it, feed it sensibly and in moderation and don't poison it with cigarette smoke (yours or anyone else's), with excess alcohol or with harmful drugs

(2) Think positively about health—make it a purpose for living

(3) Turn your thoughts away from those bodily functions (digestion, circulation, breathing and so on) which can look after themselves. Introspection leads to hypochondriasis (unnecessary and excessive worrying about our health).

THE DEVELOPMENT OF MEDICINES.

A great surgeon, the first of the moderns, was Ambrose Paré, who died in 1590, and one of his best known sayings was: "I apply the dressing, but God heals the wound." He was quite right; for until about one hundred years ago, or even less, all the physician could do in most cases was to put the patient in as favourable a state as possible to enable his body to cure itself. There were hardly any specific drugs—drugs that had a direct effect on the disease.

There was quinine, discovered by the Spaniards in America, which was specific for malaria, and there were iron (specific for anaemia) and digitalis (specific for certain types of heart disease), but otherwise nothing until the nineteenth century, when Paul Ehrlich discovered salvarsan, which is specific for syphilis. Ehrlich died in 1914, having conceived the brilliant idea of drugs, which he described as "magic bullets"—*i.e.*, drugs which, like bullets, would be aimed at the real cause of the disease. They would, that is to say, be specific.

Antibiotics (and Antibiotic Resistance).

Since then a multitude of such drugs have been discovered. For example, there were antibiotics, such as penicillin, discovered in 1928 by Fleming at St. Mary's Hospital, Paddington. Later, Florey and Chain in Oxford, helped in the 1939 45 war years by the vast resources of the American pharmaceutical industry, were able to produce penicillin available to the public in sufficient quantities by new techniques of production.

Penicillin is practically non-poisonous (although it is possible to become allergic to it, sometimes with serious results). It can kill some germs in a dilution of one part of penicillin to one million parts of water; it is effective against streptococci, the cause of blood-poisoning, sepsis in wounds, and many other diseases; and also against the germs of gonorrhoea, meningitis of certain types, and syphilis—penicillin is typically active at 1–10 ug/ml *i.e.* 1–10 parts per million. Blood-poisoning, whether from wounds or childbirth, used to be almost incurable—now the rate of cure is around 90 per cent.; gonorrhoea has an almost 100 per cent. rate of cure. In pneumonia the rate is 90 per cent., and early syphilis can be cured in a week, instead of the previous two to three years.

Unfortunately, one of the looming medical crises at the moment is antibiotic resistance. Decades have elapsed since new antibiotics have been found (but a promising discovery was made in 2015). Now in 2017, resistance to antibiotics is a global problem.

Other Types of New Drugs.

But that was only the beginning. Other antibiotics—streptomycin, tetracycline, erythromycin, and many others—have greatly reduced the terrible scourges of the human race, in particular, in the case of streptomycin, tuberculosis. The sulpha group of drugs—sulphadiazine, sulphadimidine, *etc.*—have also proved a great boon. Then there are the newer drugs which have created a revolution in psychiatry—the tranquillisers which relieve anxiety, the drugs which clear up certain types of depression, and substances such as chlorpromazine which make it possible to nurse formerly violent patients in the wards of a general hospital. The antihistamine drugs help in allergies, anticoagulants are of value after heart attacks and levodopa mitigates some of the distressing features of Parkinson's Disease.

The Safety of Drugs.

No drug, old or new, is completely safe—if we define "safe" as meaning having absolutely no potential for harm. The household aspirin, widely used in a variety of conditions for its analgesic (pain-relieving) and antipyretic (fever-reducing) qualities, can cause bleeding from the stomach and small intestine. Phenacetin, at one time a component of compound codeine tablets but now withdrawn, can—with prolonged use—damage the kidney. Chloramphenicol, a powerful antibiotic effective in typhoid fever, typhus and whooping cough, can damage the blood-forming cells of the bone marrow producing an agranulocytosis which can be fatal.

Clearly, in any one case, the doctor must weigh up the advantages and disadvantages of this or that drug before prescribing. Minor, self-limiting illnesses do not require potent, potentially toxic remedies. Chloramphenicol is rarely justified in whooping cough, but would never be withheld from a patient with typhoid fever.

Humans make up a unique species. A new chemical compound promising in animal experiments, for example, as an anti-inflammatory agent, apparently safe when given, say, to mice in a dose 100 times that required to produce that anti-inflammatory effect may, over a long period of time in us, not only have no effect but make his hair fall out or perhaps cause retention of urine.

Nevertheless, some animal species do react like humans, or vice versa, and it is possible to make reasonably accurate extrapolations from animals to man in terms of drug effect. It is also possible to estimate the toxicity of a drug on humans from its toxicity in certain animal species, but the ultimate test comes only when it is given to us.

The 1950s Thalidomide Tragedy.

Thalidomide was unique. In every animal test used throughout the drug industry at that time—it was introduced in the late 1950s—it had a clean bill of health. It was chemically related to other drugs which had been in use for a long time. Overdosage with other sedatives such as the barbiturates was common at that time, although less so now. Overdosage with thalidomide was unlikely to prove fatal. It was marketed in Europe and in Britain as a "safe sedative".

The tragic results that followed its ingestion by women in the early weeks of pregnancy are well known. Over 10,000 babies across 46 countries were born with severe deformities of limbs, internal organs or both. That effect could not have been foretold from any animal tests then in use. Since that date new drugs have been subjected to rigorous testing in various animal species to check the effect on foetal development as a statutory requirement, along with the older tests for toxicity which had always been undertaken by reputable drug companies.

The Control of New Drugs.

Briefly, no new drug or modification of an old one can be sold, whether or not on prescription, unless it has been granted a product licence by the Department of Health and Social Security (DHSS).

Many stages have to be passed to acquire that licence, from the granting of certificates to allow the drug to be tested initially in a limited way in patients in a strictly controlled manner by investigators, to permission for extension of those trials at a later date to include larger numbers of patients or more investigators, to perhaps a "monitored release"—that is, to enable its use in, say, hospitals only -to the final release on the granting of a full product licence.

Furthermore, all the stages are dependent on production of evidence relating to the safety and efficacy of the drug, evidence which may take the drug company months, sometimes years, to produce and which, of course, must be acceptable to the regulatory authority, the London-based European Medicines Agency. Trials may be stopped at any time, for example, if evidence of side effects of an undesirable nature come to light during clinical testing, or when evidence from some other similar compound indicates a likely risk in the use of the drug in question. Of course, "acceptable" means that the strict criteria which have been laid down by the specialist committees appointed to deal with all the various aspects of drug development, such as toxicology, adverse reactions and so forth, have been met.

Surveillance of Side Effects.

As well as all these rigid controls on development and testing in the early stages, there is also a scheme of surveillance for untoward side effects. These are the action, or actions, of a drug apart from its main one. Take the well-known side effect of drowsiness which occurs with certain antihistamine drugs: the main action, the one for which the drug is prescribed, is the mitigation of the effects of allergy, such as urticaria. Drowsiness would be an unwanted effect if the patient is not incapacitated and is able to do his usual job. On the other hand, some antihistamines have an appetite-stimulating effect which could, of course, be a useful attribute in certain situations or even allow the drug to be used solely for that purpose, the anti-allergic effect then being incidental.

New Surgical Advances.

Mention must of course be made of the surgical advances and progress in anaesthesia. Hardly a week goes by without operations being undertaken which seemed inconceivable even as short a time as 50 years ago. Transplantation and re-plantation (the re-attachment of severed limbs) are routine operations; haemodialysis (the 'cleansing' of blood in patients with irreversible kidney disease) is now often undertaken in the patient's own home where, with appropriate adaptation and the modern kidney machine, he or she can run the procedure—single-handed in many instances—and still keep his or her job; and the laser beam is used to deal with detached retinas or to obliterate tiny, microscopic blood vessel 'bubbles' (aneurysms) in the back of the eye while the patient is conscious and cooperative. Keyhole surgery is often the norm (*see* **Z60**). The list grows daily.

The Conquest of Disease.

As mentioned earlier, doctors and scientists have acheived notable triumphs in curing or preventing once devastating and widespread illnesses such as smallpox and polio. It is hard to realise now that polio was once so widespread and so crippling. Only three decades ago, in 1988, around 350,000 people spread across 125 countries contracted polio. Now in 2017, it is almost eradicated across the globe. The first polio vaccine was created sixty years ago. In the UK the last case was in 1982. Across the world the global eradication campaign has immunised a vast number of children (around 2·5 billion). Only in a very few places (such as Nigeria) are cases now reported. It is one of the great success stories of modern medicine.

LANDMARKS IN PUBLIC HEALTH.

1831–32	First major cholera epidemic stimulated sanitary improvements.
1840	Select Committee on the Health of Towns exposed slum conditions.
1842	Chadwick's Report on the Sanitary Condition of the Labouring Poor.
1847	First Medical Officer of Health in Liverpool. James Simpson discovered chloroform anaesthetic.
1848	Health of Towns Act established central Board of Health and local boards. Further cholera epidemic.
1853	Further cholera epidemic.
1854	Value of efficient nursing demonstrated by Florence Nightingale and Mary Seacole.
1860	First professional training school for nurses at St Thomas' Hospital.
1865–66	Further cholera outbreak.
1867	Lister developed antiseptic techniques.
1868	Invention of thermometer.
1871	Local Government Board set up to supervise poor law and public health.
1872	Public Health Act. Appointment of medical officers of health made compulsory and sanitary authorities set up.
1875	Public Health Act. Local sanitary authorities given power to enforce sanitary regulations including drainage, sanitation and water supplies.
1907	School medical examinations made compulsory and school medical services established.
1911	National Insurance Act. The Act provided insurance against sickness and unemployment to be paid for by contributions from the state, the employer and the employee. It covered those between 16 and 70 years of age, but was limited to industries where unemployment was recurrent. Maternity grants introduced.
1918	Ministry of Health established.
1929	Public Health committees set up by county and county borough councils.
1930	Mental Treatment Act made voluntary treatment possible for mental illness.
1934	Local authorities allowed to provide subsidized or free milk at schools.
1944	Government White Papers *A National Health Service*, *Employment Policy*, and *Social Insurance* accept the principles of a national health service, full employment and a comprehensive system of social welfare (following the 1942 Beveridge Report).
1946	National Health Service Act provided a free medical service for everyone, including free hospital treatment, dental care and opticians' services. The Act came into force in 1948. Doctors and dentists now worked within the National Health Service though they continued to be able to treat private patients as well. Free milk for all schoolchildren introduced.
1954	First kidney transplant.
1967	Abortion Act provides for the legal termination of pregnancy under certain circumstances. Family Planning Act allows local health authorities to provide a family planning service for all who seek it, either directly or through a voluntary body. Advice provided free with graduated charges for contraceptive devices according to the means of the patient.
1971	Abolition of free milk for schoolchildren.
1973	National Health Service Reorganization Act creates area health authorities to coordinate health services within the new local government boundaries set up in 1972.
1978	Health Services Act provides for the withdrawal of private medicine from National Health Service hospitals.
1983	First combined heart and lung transplant.
1990	National Health Service and Community Care Act provides for hospitals to opt out and become self-governing trusts; allows general practitioners to control own budgets; reorganizes system of local community care giving local authorities responsibility for care of elderly people in the community.
1992	Introduction of the Patient's Charter. Some nurses given power to prescribe drugs.
1995	Completion of "internal market" in the National Health Service; all hospital and community care other than in Scottish islands provided by Trusts.
1997	Incoming Labour government in White Paper *The New NHS* proposed abolition of "internal market", reductions in bureaucracy and more spending in specialist areas.
2000	Labour government announces massive increase in spending on the NHS with large increase in numbers of nurses, doctors and consultants, as well as firm commitments to maximum waiting times for treatment.
2008	Publication of the Darzi Report (*Our NHS, Our Future*). Debate over proposed creation of polyclinics.
2009	First-ever constitution for the NHS published, setting out the rights and responsibilities of patients and those who treat them.
2010	Coalition proposes major shift of power over NHS to GPs.
2012	Coalition Health Reform Bill becomes law.
2013	All nurses to be required to have degrees.
2014	Mounting concerns over future NHS funding.
2015	Pioneer devolution of NHS powers to Manchester region. Warnings of excess use of antibiotics.
2016	First robotic kidney transplants in UK.

THE NATIONAL HEALTH SERVICE (NHS).

If you need to find out more about NHS services, www.nhs.uk is the official NHS website that can help you. It provides free, basic information such as addresses, maps and contacts for NHS organisations. In addition, www.nhs.uk holds information about what the NHS has to offer and how you can get access to these services.

Through this easy-to-remember website you can:

* get the latest news about the NHS and current health campaigns;

* find out how to have your say about NHS services;

* learn about the history and structure of the NHS; and;

* look up performance facts and figures.

Prescription Charges.

Currently (May 2017) a charge of £8•60 is payable in England for prescriptions (except for contraceptives which are not charged). Prescription charges have been abolished in Wales and Northern Ireland. In Scotland, their abolition took effect from April 2011.

There are, however, important categories of people exempt from charges. These include children under 16, full-time students under 19 as well as men and women aged 60 or over. Pregnant women who hold an exemption certificate are also included. Diabetics are exempt as are those with such illnesses as fistula, myasthenia gravis, cancer *etc.*

Certain people on income support and other benefits are also exempt. Check booklet HC11 available from Post Offices.

The General Medical Council (GMC).

The General Medical Council regulates the medical profession in the United Kingdom. It sets the qualifications and standards required to be registered as a doctor. If found unsafe or unfit it can restrict a doctor's medical practice.

Patients may complain directly to the General Medical Council.

British Medical Association (BMA).

The British Medical Association has over 130,000 members including about 80% of the UK's practising doctors. It represents their interests, and its roles include publishing the *British Medical Journal.*

This respected medical journal is available free on the Internet (*www.bmj.com*) together with an accompanying electronic discussion forum.

Primary Care/Clinical Commissioning Groups.

Primary care describes the service you receive from the NHS staff who look after your health needs in the community. This includes your family doctor, health visitor, community nurse, community pharmacist, optician, dentist, physiotherapist *etc.*

A Primary Care Trust (or PCT for short) is a local NHS organisation, which receives money from the Government to plan and provide health services for local people. The PCT's main aim is to improve the health of local people and deliver the best quality healthcare for the population. They were replaced by Clinical Commissioning Groups in 2013.

The Health Service Ombudsman.

The Health Service Ombudsman looks into complaints made by or on behalf of people who have suffered because of unsatisfactory treatment or service by the NHS. He is completely independent. His services are free.

The Ombudsman also looks into complaints against private health providers, but only if the treatment was funded by the NHS. He can also investigate complaints about other services provided on behalf of the NHS.

Anybody wishing to complain to the Ombudsman must first have put their complaint to the NHS organisation or practitioner concerned, such as the hospital trust, Health Authority, the GP or the dentist. They will give you full details of the NHS complaints procedure and will try to resolve your complaint.

If you are still dissatisfied once you have exhausted the NHS complaints procedure you can complain to the Ombudsman.

To find out more about the NHS complaints procedure, pick up a leaflet from any NHS organisation, the NHS website or your GP or dentist's surgery.

The European Health Insurance Card (EHIC).

The free E111 form which entitled you to free or reduced-cost state healthcare if you fell ill or had an accident while travelling in a European Union (EU) country was replaced with the European Health Insurance Card from 1 January 2006. The card is free and can be applied for on 0845 606 2030 or online at www.ehic.org.uk. Check for any changes to this.

Organ and Tissue Donation.

One of the most useful things we can all consider doing is to donate our own organs. Organ donation is the gift of an organ to help someone who needs a transplant. The generosity of donors and their families enables over 3,000 people in the UK every year to take on a new lease of life. Over 80,000 patients have now received transplants.

One donor can save the life of several people, restore the sight of two others and improve the quality of life of many more. The more people who pledge to donate their organs and tissue after their death, the more people stand to benefit. By choosing to join the NHS Organ Donor Register you could help to make sure life goes on for many others. No less than 22 million people are now (2017) on the Organ Donor Register.

Organs that can be transplanted include kidneys, livers, lungs, pancreas and the small bowel. Tissue donation is the gift of tissue such as corneas, skin, bone, tendons, cartilage and heart valves to help others.

To decide whether or not you wish to become a donor after you have died is something very personal and it is important that everyone makes their own decision.

Wales has now introduced organ donor presumption. Since 2015 people have needed to opt out if they do not wish their organs to be used.

For more information you can phone 0845 606 0400 or contact www.uktransplant.org.uk.

PART II. DISEASES ARRANGED BY CAUSE OR BODY SYSTEM AFFECTED

THE INFECTIOUS DISEASES.

Introduction.

Infectious diseases are those which are caused by an invasion of the human body by organisms from outside (the word "organism" simply means living things, and we are using this word because, as will be seen later, it is not only what are known as "germs" which can cause infection). We know, too, that what is generally typical about this group is: (*a*) that the disease can be passed on from one person to another, and (*b*) that it is usually accompanied by a raised temperature or fever. Now (*a*), of course, is always true, because the definition of an infectious disease is one that can be passed on to others, but (*b*) is not always true, because a few infections produce little or no temperature, and also because it is possible to have a raised temperature (again in only a few cases) without any infection. For example, certain types of brain injury, tumour, or haemorrhage can produce a raised—or lowered—temperature, and so can the injection of some foreign substance such as milk into the muscles. This is known as "protein shock," and was at one time used in the treatment of certain illnesses.

Finally, solutions of dead germs, such as the antityphoid vaccine given to protect troops in wartime, may lead when injected to very high temperatures. But, by and large, we are entitled to suppose that the patient with a raised temperature is probably suffering from an infection.

Types of Infection.

As we have seen, it is not only germs which cause infections—so from now on we shall give germs their proper name of "bacteria." Here is a list of the chief offenders which are liable to attack our bodies: bacteria, viruses, fungi, amoebae, worms and other parasites.

Bacteria are tiny living things which can be seen only under a fairly powerful microscope. Some are grouped like bunches of grapes (*staphylococci*) or in strings or chains (*streptococci*). They are given these names because "staphylos" is the Greek word for a bunch of grapes, and "streptos" means a chain. Yet others are comma-shaped (such as the cholera vibrio), or shaped like a drumstick—a rod with a small knob at the end (the tetanus bacillus, which causes lockjaw).

Types of Bacteria. It would be a mistake to think that all bacteria are harmful; for without some species we could not survive for long. Indeed, a human being carries around ten times as many bacterial cells as human cells. Our guts team with them. Bacteriologists divide them according to their behaviour in the human body into three groups: saprophytic, parasitic or pathogenic, and symbiotic. The *saprophytic* organisms are the bacteria normally found in the skin, mouth, and intestines; they do us neither harm nor good. The *parasitic*, or as they are more usually called, pathogenic (*i.e.*, disease-producing) organisms, are the harmful ones with which we are naturally more concerned. Lastly, there are the *symbiotic* organisms, which, whilst taking something from the body, give something in return. For example, cattle would not be able to digest the cellulose of the grass they eat were it not for helpful bacteria in the lower parts of the intestines, and there are certain bacteria in the large intestine of man which produce vitamins.

Characteristics of Bacteria. Bacteria have two peculiar characteristics: each reproduces by splitting into two separate individuals as often as every twenty minutes in favourable circumstances like an open wound. If no bacterium were destroyed, one individual could produce a mass of bacteria larger than the whole world in a matter of a few weeks (since each of the offspring also divides into two, which in turn divide again— the progression goes: one gives birth to two, these two to four, the four to eight, eight to sixteen, sixteen to thirty-two, and so on—you will see, if you work it out, that in a short period the figure becomes astronomical). Fortunately, most bacteria do not find themselves in ideal conditions, so for the present the world is safe! The other curious thing about bacteria is that, barring accidents, they are potentially immortal. Under ideal conditions in which no bacteria were killed, none would die; for a bacterium there is no death from old age, no corpse except when it is actively destroyed. It simply goes on dividing, dividing, and subdividing for ever.

How, then, can bacteria be destroyed? Briefly, the answer is that most are destroyed by the natural defences of the body of whatever host they are preying on; others are destroyed by antiseptics and the new drugs; and many are destroyed when they are excreted from the body in the sputum or through the bowels and land in places where they are dried up and cannot survive —although some bacteria in such circumstances can form what are called "spores," rather like the seeds of plants, so making it possible for them to survive in a state of suspended animation for months on end until picked up accidentally by another unfortunate host. Finally, bacteria, in addition to all these possibilities, face another danger: they may themselves develop disease.

Bacteriophages. This disease is caused by even more minute organisms known as bacteriophages (viruses which affect bacteria), discovered by F. W. Twort in 1915. Attack by bacteriophage causes whole groups of bacteria (known as "colonies") to disintegrate and become harmless.

Although bacteriophage have been used in the treatment of some diseases in human beings, this method has now been largely given up, since the new drugs are infinitely more effective.

Other Spirochaetes, like bacteria, are minute organisms, but differ in being shaped somewhat like a corkscrew and in being able to move. Their progress is produced by a sideways wriggling motion. The two main diseases caused by spirochaetes are syphilis and leptospirosis.

Leptospirosis is carried by rats, and is common in those who work in mines. It is now rare in Britain, but still occurs in Egypt, and Malaysia; the infection is passed through the skin where the excreta of infected rats mingles with water on damp ground in the mine where miners kneel. Infection may also occur through eating infected food.

Viruses. Unlike bacteria, viruses are too small to be seen under an ordinary microscope. They can, however, be photographed in some cases under an electron microscope, which uses a magnetic field instead of a glass lens and a stream of electrons in place of a beam of light. Viruses cause such diseases as measles, mumps, poliomyelitis, smallpox, and chickenpox—not to mention such plant and animal diseases as tobacco mosaic disease and foot-and-mouth disease, which often have serious economic consequences. Other virus diseases are swine fever in pigs, influenza in Man, and myxomatosis in rabbits. They also cause the common cold.

Characteristics of Viruses. The main characteristics of viruses are, first, that they can only grow in living cells—unlike bacteria, which readily grow in the laboratory on plates containing a jelly made from meat, broth, gelatin, milk, and other delicacies. The scientist, therefore, must keep them in portions of living tissue kept alive outside the body. Secondly, many are so small that they pass through the pores of the finest filter. Thirdly, a first attack usually produces immunity for life. Second attacks of the common virus diseases mentioned above are very rare; but unfortunately, this rule does not apply to influenza or the common cold. Fourthly, there is reason to believe that viruses represent an extraordinary intermediate stage between the living and non-living; they can, for instance, be produced in crystalline form and yet are just as dangerous when "thawed out." Lastly, the virus diseases have proved for the most part to be little affected by the new antibiotics and other drugs, although vaccination in smallpox and the injection of sera from infected patients in other infections may give immunity for longer or shorter periods, and progress has been made in developing drugs to combat some viruses, such as herpes viruses and the AIDS virus.

Practical Virus Problems. The two great practical problems that doctors face with viruses are: (i) many viruses are unknown because of the difficulty of growing them outside the body in suitable tissue culture. They cannot therefore be conveniently identified in specimens from the patient, as bacteria can; and (ii) most are unaffected by antibiotics like penicillin. It has been a great step forward to grow viruses artificially in tissue culture, in which they are identified indirectly by the effects they have on the cultured *cells*. But since we do not know exactly how to grow some viruses (like those of infective hepatitis) many have still not been seen.

When we recover from a viral illness like chickenpox, we probably do so by producing virus-killing substances such as interferon inside our own cells. Scientists are currently searching for these substances in case they can be used, like penicillin, to cure viral disease.

Fungi. Some infections are caused by fungi—that is to say organisms belonging to the same group as moulds, mushrooms, and toadstools. Penicillin and some other antibiotics are produced from moulds, so, as in the case of bacteria, some fungi are helpful; they even help to destroy each other, as bacteria do. For example actinomyces, which can cause infection of the jaw and other tissues, is destroyed by penicillin.

Most fungal infections are trivial and limited to the skin. But, although trivial, they can be unsightly and uncomfortable. Ringworm of the scalp, dhobie itch—an infection of the groin spread by infected underclothing—and so-called "athlete's foot" are caused by a fungus.

Amoebae. Amoebae are small, single-cell organisms, the largest of which (a harmless type found in stagnant ponds in Britain and elsewhere) is just visible to the naked eye. It is about the size of the head of a pin. Amoebae move, in the species which are capable of moving, by pushing forward a part of the cell in the appropriate direction and causing the rest to flow into the advancing portion. Like bacteria, they reproduce by dividing into halves, each of which becomes a new amoeba.

The main human disease caused by amoebae is amoebic dysentery (not to be confused with bacillary dysentery).

Parasites. These may live on the skin like lice (which can carry typhus) or fleas (carriers of plague) or the parasites of scabies which burrow into the skin, or they may live part of their time in the blood or other tissues, like malaria. They often have complicated life-cycles involving other hosts (like mosquitoes) at certain stages of development.

Worms. Worms are intestinal parasites, but the only common types found in Britain are threadworms, the tiny thread-like worms which cause irritability and itching in the skin of children, less often in adults; round-worms, somewhat resembling the ordinary garden earthworm, which seldom lead to symptoms; and tapeworms, which may reach a length of 3 or even 6 m. Many parasitic worms (like parasites elsewhere) lead a double life—they spend part of their life in the human intestine and the other part in the muscles of another animal. The tapeworm, for example, whilst in the human intestine, lays eggs which pass out of the body in the excreta, and are then swallowed by pigs, especially in those parts of the world where human excreta are used as manure in the fields. In the pig, the eggs form cysts in the muscles—meat infected in this way is known as "measly pork"—and when, in turn, the meat is eaten by man, the process in the intestine begins all over again.

For a further discussion of diseases spread by parasitic worms, *see* **Z17–18**.

Russian Tape-worm. Less common types include the Russian tape-worm; this type is spread by caviare or undercooked infected fish. The small, leaf-shaped liver fluke lays eggs which are passed into canals or pools in tropical countries in the urine of infected people, hatch out and enter a water snail, and finally leave the snail in the form of small parasites which pierce the skin of bathers, whence they pass to the liver and subsequently the bladder and rectum. This is a serious condition, as is also *filariasis* (another tropical disease), for which, unlike bilharzia—caused by the liver fluke—no cure is known. The tropical disease known as *loa-loa* is caused by a variety of filaria.

How the Infection is Spread.

Infection is spread in many ways, some of which have already been mentioned. In the common fevers found in Europe and elsewhere one of the most frequent ways is by *droplet infection*—that is to say, by minute drops carrying the germs which are coughed or sneezed into the air by someone already suffering from the disease. Such droplets can be projected into the air for 3m or more, and when breathed in by someone within range infection may result. Next commonest mode of spread is perhaps by *infected food, water*, and the dirty hands of those who prepare food: cholera, dysentery, food-poisoning, and typhoid are spread in this way. Spread by *direct contact* is found in the venereal diseases (usually, but not always, spread by sexual intercourse with someone who already has the disease), and, of course, lice, fleas, and other parasites, including the scabies mite, are spread by contact with the infested individual—or sometimes with his clothes or bed linen. Spread through an *intermediary host*, whether it be lice, fleas, or mosquitoes carrying infection, or the various means adopted by worms, has already been described above, so no more need be said. Lastly, the infection may result from *bacteria already within the body*; for example, Escherichia coli, which lives in the large intestine is harmless there, but if it gets into the bladder or the ureters (the tubes leading from kidney to bladder) a quite unpleasant result may follow in the form of cystitis or pyelonephritis.

How the Body Deals with Infection.

The body has many mechanisms of defence against intruders; these can generally be divided into two types. First, non-specific defence substances such as lysozyme, an enzyme that digests bacterial cell walls, are present in many body fluids, and a system of blood proteins known as the complement cascade punches holes in bacteria to kill them. Interferons and other so-called cytokines are produced when the body's cells are damaged by infection and help other cells to resist infection. A class of blood cell, known as macrophages, responds to infection and other damage by migrating to the affected part of the body and swallows bacteria and cell debris for destruction by the powerful enzymes that they contain. Secondly, specific defences are stimulated by infection: one class of lymphocytes produces antibodies, which recognise particular parts of bacteria and viruses, neutralising them and marking them out for destruction. Another class of lymphocytes hunts for foreign cells and kills them by a variety of methods, bursting them open and leaving debris for the macrophages to clear away.

Immunisation.

Immunity can be induced by immunisation, which can be active or passive. In active immunisation, a vaccine is injected into the body to simulate the first time the body is infected with a disease-causing agent. Vaccines are made either from dead bacteria or viruses or from specially adapted strains which have lost their ability to cause disease. Passive immunisation is used when a person has already been exposed to a disease or when an effective vaccine is not available, and consists of injections of specific gamma-globulin obtained from the blood of a patient who has recently recovered from the disease concerned.

Immunology is one of the fastest-growing areas of medical research, as there are still many infectious diseases which are difficult to treat with antibodies, and manipulation of the immune system has great potential in the fight against cancer.

Antiseptics.

The earliest antiseptic was carbolic acid, used by Lister in his operating-theatre in the form of a fine spray directed throughout the operation on the wound, or sometimes in the form of steam from a kettle containing a solution of carbolic. But carbolic is dangerous, and since Lister's time many more useful antiseptics have been discovered. Acriflavine, thymol, and other old favourites have been discarded too. The various forms of carbolic are still used to disinfect drains, but, to tell the truth, the use of antiseptics nowadays is very limited. In surgery the *antiseptic* method has given way to the *aseptic* method—instead of fighting sepsis we see to it that no possibility of sepsis is present before operating; all instruments, the surgeons' and nurses' hands, the skin, are sterilised—the instruments by boiling, the dressings by dry heat, the hands by soap and water, and almost the only antiseptic used is to clean the patient's skin in the area to be operated on.

Antiseptics are used as first-aid treatment for cuts and wounds, but should be applied only once as a general rule—that is, when the wound is first received. The trouble with antiseptics is that as well as killing germs they also kill the surrounding tissues, which antibiotics never do.

Antibiotics.

Some antibiotics—penicillin, streptomycin, erythromycin and so on—have already long been used by doctors. In recent years many others have been introduced ampicillin, gentamicin, cephalexin. Indiscriminate use of these drugs (*e.g.* for trivial complaints) has led to problems, the most important being the development of resistance by previously sensitive organisms. This is now reaching crisis proportions. It is not always convenient or possible to be able to identify the particular germ responsible for an infection and determine to which drug it is sensitive, but if there is an initial clinical response, it can be assumed that the "right" drug has been used. It is important to have a full course of treatment— which usually means ten days minimum.

Other problems are hypersensitivity (allergic) reactions which can take many forms. Once hypersensitivity to one of the antibiotics has been identified (penicillin hypersensitivity is not rare) the patient must be made aware of this, and so protect himself from unwitting prescribing by another doctor. Hospital and GP records are clearly marked in such instances but it is very important that the patient himself knows.

Antibiotics are only available on prescription, at least in the UK, but medicine cupboards are full of them, accumulated from unfinished courses. Self-prescribing is tempting but ill-advised; antibiotics must always be given under medical supervision. Side effects are common and some are dangerous. Repeated use may lead to rapid overgrowth of fungi *e.g.* thrush (Candida albicans) normally present in harmless numbers in the alimentary tract with serious, sometimes fatal results.

Nowadays, the growth of drug-resistant infections is becoming a major problem. However, in 2015 the first new class of antibiotics was developed. If approved, they will combat pathogens resistant to today's antibiotics.

General Treatment of Fevers.

Fevers, a rise in body temperature above normal, may be noticeable either by a flushed face or by alternate sensations of heat and cold. A patient with a high temperature may have shivering attacks known as "rigors." Tell the doctor.

A high temperature does not necessarily (especially in a child) mean that the trouble is serious but the lay person should always treat it as such and certainly call a doctor if the patient is a child or an elderly person. The majority of fevers are of a viral origin and usually self limiting. The patient tends to improve rapidly once the temperature is controlled.

Even the trained physician finds it difficult to tell one fever from another in the early days; for most of the common fevers begin in more or less the same way. It is only when a rash or some other more definite sign becomes evident that a certain diagnosis can be made, and these may not show themselves until the patient has been feeling "run-down" and fevered for some days. A clinical thermometer is a useful tool and inexpensive to buy. Control of temperature is important, especially in young children, where a high fever may produce a convulsion. A febrile convulsion is a frightening experience for any parent, particularly as their child may have seemed quite well a few minutes previously. High temperature, twitching, and increased irritation may herald the onset.

Emergency management involves keeping the child on its side to avoid inhalation of vomit, clearing debris around the mouth, removing the clothes and sponging with lukewarm water. Get someone to summon medical help, but never leave an unconscious child alone. Above all, do not panic as the initial episode will usually soon pass.

Briefly, then, the way to treat a fever in the early stages before the doctor comes is as follows:

(1) Put the patient to bed. The child is probably better on the living room sofa where he or she will feel less isolated and is more easily observed.
(2) Give plenty of clear fluids; water, water and fruit juice, weak tea or lemonade.
(3) Give small amounts of easily digested food but only if the patient requires it.

Aspirin is no longer recommended for the treatment of feverish children, and should not be given to children under 12 years of age. This is because it has been linked to the development of "Reye's Syndrome", an acute encephalopathy or inflammation of the brain with delirium, convulsions and coma. Although very rare, "Reye's Syndrome" carries a high mortality.

Paracetamol and Aspirin. Adults with a history of peptic ulcer or chronic indigestion should also avoid aspirin because of the possible risk of a gastro-intestinal bleed. Paracetamol is now the treatment of choice to reduce temperature and relieve headache and elixir preparations are available for children. The dose may be repeated 4/6 hourly and there are no gastro-intestinal side effects.

Medicines containing Paracetamol should be stored in a safe place as overdosage, accidental or otherwise, may cause liver damage without initial drowsiness or loss of consciousness. Symptoms may not be apparent for a number of days.

Other methods of cooling a feverish patient involve removing excess clothing, administering tepid baths or sponging with lukewarm water. Simply standing at an open door and allowing the cool outside air to waft around the feverish child, or the use of fans, can have an immediate effect.

THE INFECTIOUS FEVERS.

The remarks made above apply to the management of *any* fever, and we are now going to discuss particular infectious diseases, beginning with the common childhood fevers, then passing on to less common ones, tropical diseases, and worm and parasitic infestations.

The common infectious fevers are caused by bacteria or viruses, and it is useful to know the meaning of the following terms: *incubation period* is the time which elapses between being infected and developing symptoms; *prodromal period* is the time which elapses between the end of the incubation period and the appearance of a rash; *quarantine period*, the maximum time during which a person who has been in contact with the infection may develop the disease—it is usually two days more than the incubation period; *isolation period* is the time a patient is supposed to be isolated.

Virus Diseases.

First, we shall take the common virus diseases, measles, chickenpox, and rubella or German measles, then the other virus diseases, mumps, infective hepatitis, viral pneumonia, and some other conditions which do not always produce a typical rash as in the case of the first three.

In most of these fevers there is a long incubation period, and one infection gives immunity for life.

Measles. The incubation period is 10–11 days. The first sign is the appearance of symptoms rather like a severe cold. The eyes become red, and exposure to light is unpleasant, the nose runs, the throat becomes inflamed, and a dry, harsh cough develops. There may be headache and the temperature rises to 39°C or more. Usually the patient is a child, and especially typical is the development of so-called Koplik's spots, which are small, bluish-white, raised spots seen on the inside of the cheek at the back of the mouth. The rash begins on the fourth day of the prodromal period, *i.e.*, 14 days after the initial infection. It shows on the forehead and behind the ears, spreading within a day downwards over the whole body; in another two days it starts to disappear, but often leaves behind a sort of brownish staining which may last for one to two weeks.

Measles can be serious, especially in very young children because of its complications, such as bronchopneumonia and infection of the ear, which can now be treated with antibiotics. These drugs have no effect on the measles virus, but only on the secondarily invading bacteria which have invaded the lungs and ear during the illness. The illness can be attenuated or lessened by injection of antibodies (gamma globulin) from an immune adult, and this is often worth while in the very young. After the MMR vaccine was introduced in 1988, measles almost disappeared in Britain but is now reappearing. This was very apparent in the serious Swansea outbreak in 2013. Immunisation rates in Britain had fallen after the unfounded scare over the MMR vaccine, leaving many children vulnerable. Globally, also, measles is making a comeback (around 145,000 people died from measles in 2013 alone). It is known as the silent killer.

Rubella or German Measles. Incubation period 14–19 days. A mild fever, similar to measles except that the rash is usually the first sign that anything is wrong, and the temperature is rarely above 38°C. The eyes may be pink, and there are enlarged glands at the back of the neck. The rash disappears completely in thirty-six hours. There are no complications.

German measles, in itself, is harmless, but if a woman gets the disease in the early months of pregnancy malformations in the child may appear at birth. Vaccination is advised if a girl has not contracted the disease by the time she reaches puberty. There is no special treatment.

Since April 2016 pregnant women have no longer been screened for rubella.

Chickenpox. Incubation period 14–15 days, but may be more variable. In children chickenpox is a mild fever which begins with the appearance of tiny blisters on the chest and back. These later spread outwards to the legs, arms and face, and cause itching. Treatment is the general one for fevers already described. Calamine lotion or dusting powder will be helpful for the irritation, and the child's nails should be cut short to prevent scratching and infection of the spots. Whereas children are usually little bothered by chickenpox, young adults may be much more drastically affected—a temperature of 40°C is not uncommon, and then there may be severe headache.

Shingles is a disease that sometimes follows chickenpox – usually by many years, and results from reactivation of the chicken pox virus, which 'hides' in the spinal cord after a childhood infection. *See also* **Z49**(**1**).

Mumps. Incubation period 17-18 days. The typical appearance of mumps is a swelling in the salivary glands in front of the ears which makes the face look full. This causes pain later on, and it may be difficult to open the mouth. Temperature is not usually high (about 38°C). Although uncomfortable, mumps is rarely dangerous, but orchitis—swelling of the testicles—is sometimes a complication, especially if the infection occurs beyond childhood. Fluid diet should be given if eating is painful, with mouth-washes, and rest in bed. Mumps is an acute viral illness. It is very often spread by coughs and sneezes.

Infective Hepatitis. "Hepatitis" means inflammation of the liver, and infective hepatitis, which is much the commonest cause of jaundice in young adults, is a viral infection of the liver. The main symptoms are fever, followed by jaundice, which is first noticed in the whites of the eyes as yellow staining, then in the skin. The urine becomes coloured also, and this is most easily noticed if, on shaking in a bottle, the froth shows coloration. If the froth remains white, no jaundice is present. Treatment is a matter for the doctor, but great care should be taken, both by the patient and those in contact with him, to wash the hands thoroughly after urinating or defaecating, after handling utensils from the sickroom *etc.*, for the disease is very infectious.

Hepatitis A is spread in faeces (*i.e.* by poor hygiene), while Hepatitis B and C are spread in blood or saliva (*e.g.* needle sharing). There is a vaccine available for Hepatitis A and B, and people at risk of exposure to infected people should consider it. Perhaps 220,000 people in Britain have Hepatitis C, but only one in ten know they are infected. Cases are rising. A new form of treatment with Pegasys and Ribavirin will now give optimum results in less than 24 weeks. Hepatitis C was identified in 1988.

Today there are estimated to be *c.* 135 million people in the world with Hepatitis C and *c.* 350–400 million with Hepatitis B (that is *c.* 500 million people, 1 in every 13 on the planet).

Hepatitis A is one of a set of viral diseases of the liver, of which seven - Hepatitis A to G - have now been identified. More may follow.

Viral Pneumonia. Pneumonia is usually caused by bacteria, and when we speak of pneumonia, that is the type we ordinarily refer to. Viral pneumonia can be caused by a variety of viruses. There is no specific treatment so far, and since diagnosis is a specialist matter little more need be said except that the symptoms in general resemble those of ordinary pneumonia. Although there is no specific treatment for virus infections of the lungs, it is always worth while trying antibiotics in view of the possibility that the lung condition may be caused by a secondary invasion of bacteria.

Influenza. While serious epidemics of influenza take the form of a very dramatic and often fatal disease—for example, the epidemic of "Spanish 'flu" which followed the First World War killed more people than the actual fighting—the milder type more usually seen is difficult to distinguish from the common cold. In fact, many people who complain of "a dose of the 'flu" are suffering from simple colds.

However, a sudden onset, aching in the muscles of the back and legs, and redness of the eyes, would suggest influenza, and especially typical is the depression and weakness which follow influenza but not a cold. The measures suggested above for the general treatment of fever should be applied; but the depression and weakness which follow influenza may need special treatment by the doctor. Effective vaccines are now available, and are particularly recommended for the elderly, though immunisation must be carried out each year to overcome the propensity of influenza viruses to change the proteins in their "coats." The search is progressing for a one-shot 'holy grail' vaccine to protect against all types of influenza. A universal flu-jab is now very close.

Colds and Sinusitis. Although we all think we know what a "cold" is, the issue is not so simple; for the symptoms of fever, running nose, and a run- down, "headachy" feeling are to be found in many illnesses. They may be observed, as we have seen, in the early stages of measles before the arrival of the rash, or in a number of other fevers, such as whooping cough. Mild attacks of influenza (*see above*) may resemble the common cold, and blocking of the nose with discharge and fever may be due to *sinusitis* although here there is usually pain above, between, or below the eyes.

Colds can be caused by any one of more than 100 different viruses known as "rhinoviruses" This is why a single cold does not confer immunity on the sufferer. It is probable that you will not catch a cold from the same virus, at least for the rest of the year, but there are all those others waiting to infect you. We may get over 100 colds in our lifetime, but we never get the same one twice!

Polio, or **Infantile Paralysis** as it used to be known, is caused by a virus which has a particular affinity for the nerve cells of the spinal cord and which results in paralysis of those muscles under the control of the particular group of cells infected. Rarely, the infection is widespread in the nerve tissue causing paralysis of muscles of swallowing and respiration as well as those of the trunk and limbs. The usual pattern is for a single muscle group to be affected, for example, the muscles controlling the movements of the arm at the shoulder. Such paralysis may be transient with complete recovery, partial with some residual weakness, or total, leaving a wasted "flail limb".

At one time in this country epidemics of poliomyelitis were common, mainly affecting children and young adults. There is no doubt that mild forms of the disease were always occurring in very young children, forms never diagnosed as such but conferring a natural immunity in later life.

In common with other infections, poliomyelitis begins with a mild or moderate fever, with a sore throat, headache, nausea and perhaps actual vomiting, some five to 10 days after contact with the virus. There may be rigidity of the neck muscles. Paralysis, if it occurs, will become apparent about the second or third day of illness. This stage may last two or three weeks, by which time the temperature will have subsided and the paralysis started to improve. There is no specific treatment and medical care is confined to symptomatic relief. Difficulty with swallowing and breathing calls for special nursing measures. In severe cases, artificial means of maintaining respiration may have to be continued for months, or for the rest of the patient's life. Many severely paralysed polio victims of the post-war epidemics —the self-styled "responauts"—depend for their lives on artificial respirators ("iron lungs").

With the development of the oral vaccine early in the 1960s, the disease has now virtually disappeared from Great Britain. It is still found in such countries as Afghanistan and Pakistan.

Smallpox. Once a terrible scourge, now eradicated in the UK. The less serious form of the disease, *variola minor*, is still found in some parts of Africa, but all the signs are that it, too, has finally been eradicated. The last case of *variola major* occurred in Bangladesh in 1975, except for at least one accidental infection in England in the 1980s. With the disappearance of the disease vaccination will become unnecessary; however, the WHO plans to store vaccine (which can be done almost indefinitely at a temperature of −20°C) in sufficient quantities to vaccinate many millions of people should the need ever arise again.

Glandular Fever. Sometimes called infectious mononucleosis, since one of its features is an increase in a certain type of white cell—the monocyte—and a change in its microscopic characteristics. It is caused by a virus (the Epstein-Barr), predominantly affects young children and adults and although often taking a protracted course, it is not in itself a serious infection. The main symptoms are fever, enlargement of lymph glands in the neck and a sore throat. A transient body rash may be seen occasionally, particularly during or after the treatment of the sore throat with penicillin or one of its synthetic cousins such as ampicillin. Diagnosis without laboratory tests on the blood (the Paul-Bunnel test) may not be easy although the combination of sore throat, swollen neck glands and a rash is highly suspicious. The disease is self-limiting and rest is normally the only treatment.

Rabies. Finally, we shall deal very briefly with a number of less common virus diseases, beginning, as is appropriate, with *hydrophobia* or *rabies*, since it was in this infection that the great French scientist Louis Pasteur (1822–95) showed the possibility of prevention by vaccination.

Rabies is spread by the bite of infected animals, usually dogs, cats, or wolves, who are driven mad by the disease; in Trinidad, however, it has been spread by vampire bats. It is thus a classic *zoonosis*, an illness transmitted from animals to people. Those who are bitten usually show no symptoms for six weeks or more, but sooner or later convulsions and delirium arise, which within four to five days are fatal. In essence, rabies is a form of brain inflammation. Around 60,000 people a year die of the disease, 40,000 in India.

There is no cure once the symptoms have developed, but antirabies serum, followed by antirabies inoculation as soon as possible, prevents illness in the majority of cases. Dogs should be muzzled in areas where the disease is common, but quarantining imported dogs has made the infection almost unknown here. Effective immunisation is now available.

Leishmaniasis, or Sandfly Fever, **Dengue**, or breakbone fever, and **Trench Fever** are all somewhat similar conditions in that they resemble influenza and are rarely fatal. Leishmaniasis is found in every continent except Australia. They are all due to viruses, spread in the first case by sandflies in tropical climates; in the second by mosquitoes in tropical climates; and in the third by lice in temperate climates. Urban sprawl in the developing world is also blamed for the spread of dengue. Cases in the UK are rising from travellers in S.E. Asia and the Far East. Around 390 million people worldwide become infected with dengue fever annually, causing around 25,000 deaths. Dengue is the world's most common insect-borne virus. It is also spreading. Symptoms include fever, headache, muscle and joint pains and a skin rash. An experimental dengue fever vaccine was launched in 2016 in the Philippines.

Yellow Fever. Yellow fever is carried by a mosquito known as Aedes, common in South and Central America and in parts of Africa (a massive outbreak occurred in Angola in 2016). For its spread, it therefore needs: a hot climate, the Aedes mosquito, and an infected person.

In yellow fever there is a sudden high temperature, aching of limbs and head, jaundice, and black vomit; the pulse-rate falls as the fever rises. Previous vaccination seems to be preventive if undertaken in time.

Zika Virus. *See* **Z61**.

Ebola Haemorrhagic Fever. *See* **Z62**.

AIDS. AIDS stands for acquired immunodeficiency syndrome, and is caused by the human immunodeficiency virus (HIV). AIDS has become a terrible affliction for the human race, and was first described in 1981. In some areas of the world, AIDS is becoming the scourge of the 21st century.

The statistics are frightening. Since 1981, over 30 million people have died from AIDS. Around 36 million are now infected. There are 15 million children worldwide who have lost one or both parents to AIDS. Over 5 million people have AIDS in South Africa, while Nigeria has around 4 million. AIDS is also a scourge in India. The number of new cases in the UK is rising. A record number of people—103,000, with *c* 6,000 new cases each year—are living with HIV in Britain.

Infection occurs by intercourse, the anal variety apparently being the more dangerous, by direct transmission through infected blood, and congenital transmission from mother to baby.

Thus, the major risk factors for AIDS are male homosexuality, needle sharing by intravenous drug abusers, haemophilia, and having an infected mother. Heterosexual intercourse is also an important mode of spread, especially among prostitutes, who are the most promiscuous members of communities. AIDS can be avoided by restricting sexual relations to the one you trust, and by avoiding *any* contact with other people's blood.

HIV damages the T-lymphocytes that are responsible for protecting the body against infection, with the result that the sufferer becomes prey to a variety of otherwise rare infections such as *Pneumocystis carinii* pneumonia, as well as some rare tumours, particularly Kaposi's sarcoma and lymphomas. The incubation period can be very long, and the first signs are often lethargy, weight loss and swelling of the lymph glands.

There is as yet no effective vaccine (although hopes of victory over AIDS are now rising). Treatment currently consists of taking a number of different anti-viral and enzyme inhibiting drugs. These have numerous side-effects.

Conclusion.

There is no specific cure for most viral diseases, though several can be prevented by immunisation or by social control of the creatures carrying the virus and by the use of common day-to-day hygiene, and drugs are beginning to be introduced against a few viruses. Incubation periods are generally of the order of days, though in the case of the AIDS virus can be measured in years. Where active immunisation is not available, passive protection with gamma globulin is an effective alternative.

Bacterial Diseases.

Bacterial diseases differ from virus infections in a number of respects; their incubation period tends to be shorter: having the disease once does not often confer lifelong protection; and unlike virus diseases, most bacterial diseases respond to one of the antibiotics or sulphonamides. In some cases it is possible to inoculate against the disease to prevent it occurring, as is possible with some of the virus diseases.

Scarlet Fever and Other Streptococcal Infections. In the days before the arrival of chemotherapy (sulphonamides and antibiotics), streptococci were very much feared and even caused a high mortality, particularly in such susceptible groups as children, and mothers and babies in maternity hospitals. They are still taken very seriously in the latter and rightly so. All signs of infection, such as fever, during the puerperium (the period following childbirth) must be promptly dealt with by a doctor, and only occasionally now is there real cause for anxiety provided treatment is prompt.

Scarlet fever is much less common and very much less serious an illness than it used to be, partly because of the effective treatments available today, but also because of a definite but unexplained reduction in its severity. Perhaps the streptococcus has changed, and certainly the improved physical condition of people who are now much better fed and housed than they were, has helped to ward off the terrors of this disease as of so many other infections.

The disease, which is more common in children, begins with a sore throat and rash. Nowadays treatment with antibiotic drugs usually produces fast recovery in the patient. However, the number of new cases in the UK is now rising fast and there are occasional serious outbreaks. In 2015 scarlet fever cases in the UK reached a 50-year high, particularly among children.

The importance of streptococcal infections has shifted from the initial infection, such as a sore throat, to some serious conditions which occasionally arise as a result of some form of delayed sensitivity to the bacteria. Acute rheumatism or rheumatic fever (not to be confused with ordinary aches and pains nor with rheumatoid arthritis) occasionally arise in people who have had a sore throat a few weeks before. Since the streptococcus is not the direct cause of the damage which may consequently occur in the heart or kidney, the antibiotics are no answer except sometimes to keep off further streptococcal invasions.

Diphtheria. This used to be an extremely serious disease, but immunisation has made it almost unknown; it is important, therefore, that all children should be immunised. Many modern doctors have never seen a case because it has become so rare, and in spite of the propaganda of certain ill-informed people, this saving of children's lives is entirely the result of nationwide inoculation.

The following description is of historic interest only, and will remain so if a high level of inoculation is kept up by parents.

In a typical case of diphtheria the incubation period is about three days; the patient is a child who becomes ill and pale-looking (*i.e.*, the onset is not sudden, as in many fevers, but insidious); the temperature is only slightly raised to, perhaps, 37° or 38°C, and although there may be no complaint of sore throat, examination will reveal inflammation with—and this is typical of diphtheria -a grey membrane spread over the tonsils, the palate, and the back of the mouth generally. The diphtheria germ does not spread within the body. It stays at the place where it entered (in this case the throat) and sends its toxins throughout the body.

Even after the acute phase is over the patient must not be allowed to walk, because the diphtheria toxin is particularly poisonous to the heart. The ordinary rule is several weeks in bed.

Diphtheria also occurs in the larynx—in pre-inoculation days many children choked to death with this form of the infection; in the nose; and, although this is not generally known, wounds can be infected.

Diphtheria may lead to paralysis of the throat, with difficulty in speaking or swallowing, and paralysis of the eyes or limbs; these are due to neuritis caused by the influence of the toxin on the nerves.

Whooping Cough (Pertussis). For many years whooping cough was regarded merely as a bother to the patient and a nuisance to others, as, in fact, a trivial disease. Unfortunately, this is not so; because statistics show that it caused more deaths than polio, diphtheria, scarlet fever, and measles put together.

Whooping cough begins in a child as an ordinary cold with cough and slight fever, and this stage lasts for a week or ten days. Then the "paroxysmal stage" begins as a series of coughs following in rapid succession, during which time the patient is unable to breathe. The "whoop" is caused by the noisy indrawing of breath when the fit stops. The face may become blue and congested. Bronchitis is usually present, and bronchopneumonia may result as a complication, so inoculation of all children before the disease has a chance to strike them is most important.

Once whooping cough has begun, there is no specific treatment, although modern drugs can reduce the frequency of the fits of coughing. The antibiotic chloramphenicol has been used for this disease, but the general opinion is that it is ordinarily of little benefit. The cough may last for at least a hundred days. There is an effective vaccine. Cases of whooping cough are now on the increase as the germ is fast-evolving.

Typhus. This disease used to be known as "jail fever," because it was frequent in prisons; but overcrowding, poverty, and bad hygienic surroundings anywhere are suitable conditions for epidemics of typhus. Improved conditions in industrialised countries have made it unusual, since typhus is carried from one person to another by infected body lice. It is due to the organism *Rickettsia prowazekii*, a very small type of bacterium.

Typhus comes on suddenly with a rise in temperature to about 39°C, but within four days it may be as high as 42°C. There may, or may not, be a rash at this time, and in the second week, when the temperature is at its highest, there is delirium, weakness, and a feeble pulse. The typical typhus rash appears about the fifth day as reddish blotches on the chest, abdomen, and wrists.

Typhus is, needless to say, very serious but responds to modern antibiotics. Preventive measures are directed towards eradicating lice.

Psittacosis. This disease which is of interest mainly in that it is spread by birds of the parrot group, such as parrots, lovebirds, macaws, and the rest is caused by chlamyclia, which are similar to bacteria. It occasionally occurs here in people who have been in contact with birds of this type, and is serious both to the bird and to its owner. Quarantine regulations greatly reduced the risk of infection in Britain. Concern over renewed outbreaks, not only of psittacosis but a number of economically important diseases such as fowl pest, led to their reintroduction in 1976.

The symptoms of psittacosis are fever, cough, and bronchitis. The disease is especially dangerous to old people, but it responds to the same antibiotics as typhus.

Tuberculosis (Consumption). No disease is more difficult to describe than tuberculosis; for, like Streptococcus or Staphylococcus, the tubercle germ can attack many parts of the body and manifest itself in many ways. Furthermore, it is a widely spread disease, infecting not only humans but also cattle, birds and reptiles. In Britain, even now, around 9,000 people are still diagnosed with TB each year. Many of these come from South Asia and sub-Saharan Africa. The number of cases is rising. Worldwide, annually, around 1½ million die of TB (*i.e.* 5,000 every single day). Many millions more carry dormant TB which can become active at anytime. Here were we shall be concerned with those types common to man—the human and bovine (*i.e.*, the type found in cattle which can be spread to man by infected milk).

The tubercle bacillus is particularly hardy, so that when coughed or spat out on the ground it continues to be infectious for a long time. Infection is therefore caused by: (*a*) drinking infected milk; (*b*) droplet infection from aerosols produced by coughing; (*c*) breathing in infected dust. In other words, tuberculosis is caused by absorption through either the lungs or the intestines; the former is common in adults, the latter in children.

The question arises: what conditions predispose to TB—why do some people get over the early infection and others not? There are two answers to this question: one is certain—that those who are impoverished and do not get enough food are liable to TB; the second is not so certain—that mental stress plays some part. Stress causes a general reduction in immunity, predisposing the body to several infections including TB.

In children, lung tuberculosis is not common, but tuberculosis of the bones and glands is, as is also infection in the abdomen, the kidney or spine, and, worst of all, tuberculous meningitis. These are often of the bovine type from infected milk. Ordinarily, TB in children is less serious than adult infections; but tuberculous meningitis used to be almost invariably fatal until streptomycin was discovered.

Adult Tuberculosis usually occurs in the lungs or the pleura—the thin membrane surrounding the lungs. In younger people miliary tuberculosis, which is a form of TB blood-poisoning or septicaemia, is a very serious condition, and the infection spreads quickly throughout the body.

Lung infection begins gradually in someone who has previously felt unwell. There may be cough, and later blood-stained sputum (although blood which is coughed up does not necessarily prove that TB is present). Whatever means of treatment is used, the struggle between disease and patient is likely to be fairly long, but the outlook is now good. The closure of the Swiss sanatoria is due partly to modern disbelief that air in one place is better than that in another, but mainly to improved treatment.

Prevention depends on legal action ensuring tuberculosis-free herds of cattle; on control of spread of the disease by those "open" cases who carry germs in their sputum; on the use of vaccination in childhood with BCG vaccine (which you can ask your doctor about).

Many methods are used in treatment. TB is now a fairly rare disease in developed countries, but there are worries that the emergence of antibiotic resistant strains will lead to an upsurge in its frequency. In Britain, for example, TB can be found in some London boroughs at quite worrying levels. A quick, cheap and accurate blood test for diagnosing TB is now being tested.

Septicaemia. This is more usually known as "blood-poisoning." This occurs generally by spread from some septic area such as a wound (or even a small prick), after childbirth, or any place where certain germs have got admission to the body.

The most usual germ is the Streptococcus, though the pneumococcus—which ordinarily causes pneumonia—and the Staphylococcus may also cause septicaemia.

In septicaemia, the bacteria damage the blood vessels, allowing blood to leak out under the skin. This leaking causes marks on the skin – a rash of red or brown pin prick spots, purple bruises or blood blisters - and reduces the amount of blood reaching vital organs such as the heart and brain.

Fever comes on suddenly and rises rapidly with headaches, sweating, and shivering. The patient is obviously very ill, and later there is wasting and delirium. The white blood cells increase in number. Septicaemia sometimes occurs without any apparent local infection in those who are weak and debilitated. A simple bedside test for blood poisoning is now nearly ready.

Pyaemia is a type of septicaemia which leads to the formation of numerous abscesses throughout the body. Its symptoms are the same as described above, except that the causative germ is usually the Staphylococcus, and abscesses are found which may need surgical treatment.

However, in both conditions the state of affairs has been revolutionised by the use of antibiotics; cure is now the rule rather than the exception.

Septicaemia should be suspected when any small wound or cut is followed by high temperature and the symptoms described above.

"**Toxaemia**" is the word used when the germs stay in their original position and go on to produce symptoms by spreading their toxins throughout the body. Tetanus, diphtheria, and some kinds of childbirth infection come into this category; the symptoms may vary from mild disturbance to severe illness.

Meningitis means inflammation of the meninges, the covering which, like a layer of plastic, lies over the brain and spinal cord, just as the pleura covers the lungs and the peritoneum covers internal organs in the abdomen. (Hence inflammation of the pleura is known as pleurisy, and inflammation of the peritoneum as peritonitis.)

Various germs may cause meningitis, for example, some viruses, the bacillus of tuberculosis, the pneumococcus, which ordinarily causes pneumonia, and the Streptococcus or Staphylococcus, but often the word refers to *meningococcal meningitis* (caused by the Meningococcus bacteria) occurring at times as an epidemic.

It is commonest in a person's years from infancy to the early twenties, and begins suddenly with headache, vomiting, and fever. The temperature rises quickly, and pain develops in the back and legs; on the second or third day a rash appears on the body, and particularly on the inside of the thighs. Later there is stiffness of the neck, the head may be drawn back, vomiting persists, and the headache can be so severe as to cause the patient to scream with pain.

Fortunately, this type of meningitis (and most of the others) respond to treatment with antibiotics, so the risks are now very much less.

New vaccines are being introduced, but these do not protect against all types of meningococcal meningitis. One new vaccine now available protects against group C meningitis and septicaemia. Also being developed is a blood test that can diagnose meningitis within hours.

In 2013 a vaccine against meningitis B was licensed in the UK and Europe. Since 2015, all babies in England and Wales have been offered a meningitis B jab. A new aggressive strain of meningitis W is now being found in Britain. University students are at particular risk.

Pneumococcal Meningitis is an unusual complication of pneumonia, and the septic types (*streptococcal* or *staphylococcal*) arise either following an infected fracture of the skull or from infection of the ear or mastoid.

Tuberculous Meningitis was originally always fatal, it is now treatable with streptomycin.

All these diseases are very much a matter for specialist and hospital treatment, but it is worth while mentioning viral meningitis, in which, although all the symptoms of meningitis are present, recovery without specific treatment is invariable.

Tetanus is usually known as "lockjaw" because there may be difficulty in opening the mouth, although this is simply part of a spasm of all the muscles of the body. The tetanus bacillus is found in rich soil—hence the disease is less common in desert areas—and tetanus resembles rabies in that: (*a*) it enters at a wound; (*b*) it affects the nervous system; (*c*) it results in fits and ultimately death.

However, active immunisation with TT (tetanus toxoid) has resulted in the disease becoming uncommon, and even when developed, treatment with antitoxin, sedatives, muscle relaxants, and antibiotics may lead to cure.

The bacillus is anaerobic (*i.e.*, does not use oxygen) and is most likely to occur in such situations as when a man digging manure or working in his garden sticks a fork through his foot.

Brucellosis falls into two types: melitensis, which infects goats, and abortus, cattle and pigs. Man gets the disease by close contact with or drinking the milk of infected animals.

In the past, brucellosis was sometimes known as undulant fever, as the fever goes up and down for two to three weeks; it may then go down and rise again, persisting for many months. The disease may occur in Britain, but modern drugs are on the whole successful. A striking feature of the disease is the combination of a high temperature with an appearance of relative well-being.

Glanders (**Farcy**) is another disease spread by mammals (in this case horses). In glanders there is discharge from the nose and sometimes pneumonia. Occasionally the disease is fatal. In farcy abscesses form, usually along the lymph vessels. Both conditions are very contagious, and treatment is a matter for a specialist; infected horses should be destroyed.

Cholera. Cholera could be classified under the head of food-poisoning, because it is mainly spread by infected water (however, like typhoid, it can also be spread by flies, infected food, and carriers); it could also be classified as a tropical disease, since, although it used to be found in Europe, it is now mainly rife in India where it is indigenous.

Cholera is caused by a vibrio, which is a spiral bacterium, and can be prevented by early inoculation and care over food supplies—boiling water and milk, washing uncooked foods in chlorinated water etc. The highest cholera rate in the world is in Haiti.

The fever begins in the usual way with a short incubation period, followed by abdominal pain, severe vomiting, and diarrhoea. Later with the loss of fluid from the body there may be cramps in the muscles, diarrhoea increases, and the motions become of the typical "rice-water" type —*i.e.*, there is no solid matter, and the appearance is that of water to which a little milk has been added. This stage is followed by collapse, with low pulse and cold hands and feet. Death, if adequate treatment is not available, results in about 70 per cent. of cases.

Cholera can generally be survived simply by replacing the water and salts lost in the diarrhoea, along with antibiotic therapy.

Anthrax. The bacillus of anthrax, like that of tuberculosis, can exist outside the body for long periods, and, like that of tetanus, then takes the form of spores or seed-like bodies. It is spread by infected cattle and horses, which get the disease from eating grass containing spores.

In human beings the form the disease takes depends on where the germ alights. Cutaneous (or skin) anthrax arises from cuts or fly bites, which may cause a large sore like a boil. It is usually curable with antibiotics. Inhalation anthrax sometimes develops in those who inhale the dust from infected hides or wool (hence the name 'wool-sorters' disease," which is a form of bronchitis with blood-stained sputum); it may arise through eating infected meat, causing intestinal anthrax.

Both intestinal and inhalation anthrax are often fatal, but now the genetic code of anthrax has been cracked there is new hope for a cure.

In Russia the disease is known as the Siberian plague. Anthrax spores have survived in the frozen carcasses of animals in Siberia for hundreds of years.

Food Poisoning Diseases.

Strictly speaking there is no such thing as "food poisoning" if one is thinking of "poisoning" in terms of anything apart from germs. All food poisoning is caused by infection of food with bacteria and by no other cause—unless of course, we are thinking of the kind of poisoning which is the concern of the lawyer rather than the doctor!

Here we are considering those diseases which are commonly spread by contaminated food or drink. First, we shall deal with typhoid, paratyphoid, and dysentery -uncommon here in Britain, although Sonné dysentery is fairly frequent. Then there is gastro-enteritis (which means irritation of the stomach and intestines), which is caused by staphylococci and the germs of the salmonella group, and lastly botulism, which is rare.

Typhoid and Paratyphoid. These diseases are spread by infected water, food, or hands—especially uncooked food, such as milk, salads, oysters, and shellfish. Flies, too, play some part in spreading the disease. Some people are "carriers" and carry and excrete the germs without being themselves affected; for example, "Typhoid Mary," a carrier in the USA in the early years of the 20th century.

Deaths from typhoid, still 332 per 1,000,000 in 1870, fell to 198 per 1,000,000 by 1900. In the 1920s the death-rate was only 25 per 1,000,000, and now it is even less in the UK (although it is rising again, probably due to exotic foreign holidays).

Typhoid fever begins like most fevers with headache, raised temperature, and general feeling of unwellness. This stage lasts about a week, and then the rash appears in the form of rose-red spots on the front of the chest and abdomen and on the back. In the second week there is great weakness, sometimes diarrhoea, flatulence, and mental dullness, together with dry and cracked lips and tongue. The third week is the week, in hopeful cases, of gradual decrease in temperature and other symptoms, and the fourth week is the week of convalescence. Complications are perforation of the intestine (which needs surgical treatment), delirium, and bronchitis. Treatment is with chloramphenicol.

Dysentery. Dysentery may be caused either by a bacterium or an amoeba; the first type is known as *bacillary dysentery*, the latter as *amoebic dysentery* (which is dealt with under tropical diseases). Infection is spread in much the same way as in typhoid. There is high fever, abdominal pain, and diarrhoea, at first consisting of faecal matter, then blood and mucus. In severe cases the death-rate used to be over 20 per cent.

Dysentry is caused by several species of bacteria of the genus *Shigella*.

However, in all these infections sulphaguanidine, ampicillin or tetracycline bring rapid relief, but care must be taken to avoid infection of other people.

Diarrhoea and Vomiting. Leaving out typhoid and paratyphoid fevers and dysentery, there is a common group of infections known as "D&V"— diarrhoea and vomiting. In Britain D&V is mostly due to:

(1) Salmonella infection.
(2) Staphylococcal infections.
(3) Other bacteria, ordinarily harmless, such as Escherichia coli, when present in sufficient numbers.
(4) Various viral infections, *e.g.* rotavirus.

Scientists have now developed a vaccine patch that can reduce the risk of traveller's diarrhoea ("Delhi belly"). Diarrhoea still claims the lives of 600,000 people annually in India.

Salmonella Infections are the most serious of this group; they affect the small intestine and produce vomiting, severe abdominal pain, and diarrhœa. These symptoms occur about one day after eating infected food and usually clear up within about two weeks, but occasionally death results. Salmonella bacteria are most likely to be found in meat, egg powder, vegetables, and ducks' eggs. About 100,000 cases are now reported annually.

Staphylococcal Food Poisoning has greatly increased in recent years, so it is important to know what circumstances are likely to cause it. Staphylococci are liable to grow in milk products, such as ice-cream and cream buns. Food poisoning from staphylococci is seldom severe, and recovery takes place in about a week. Nevertheless, it is extremely infectious, and causes a great deal of lost time in industry and temporary illness in institutions; for it is in such situations that it is most likely to occur. The reason for the increase in staphylococcal food poisoning has nothing to do, as many people suppose, with greater use of canned foods, but it has much to do with the greater use of communal feeding and canteen meals. It is *possible* for bacterial toxins in infected food to bring about illness even when the canning process has killed the bacteria, but it is certainly extremely rare. Canned foods, in fact, are much safer than so-called "fresh" foods in this respect—except when they have been opened, left about, and then re-heated. The same applies to the re-heating of any kind of food.

The real enemy is the canteen worker with a boil, a discharging nose, dirty hands, or a septic finger. Occasionally food may be infected in the larder by rats or mice, but the sort of canteen or restaurant where this can happen has little to commend it. Frankly, these infections are caused by dirty or stupid people who do not realise that their sore finger or boil can become someone else's diarrhoea and vomiting. Where children are concerned, the outlook is potentially more serious. Infection is much more common in artificially fed babies or in older children who eat infected ice-cream. However trivial the condition may seem, diarrhoea and vomiting with fever in a child should never be ignored. Those in charge of canteens or restaurants must ensure that staff is supervised, that anyone with a septic infection is put off duty, and that all know about washing after visiting the lavatory and absolute cleanliness.

Bacilli normally present in the intestine, such as Escherichia coli, can cause infections if absorbed in large amounts, or if of a different strain from those in the patient's intestine. They are not usually serious.

Botulism. Now uncommon, botulism is caused by a germ, clostridium botulinum, which is peculiar in that, like tetanus, its poison attacks the nervous system rather than the intestines, resulting in fits, double vision, paralysis beginning in the face and spreading downwards, and difficulty in swallowing.

It is found in tinned fruits or vegetables containing the toxin even when the germ has been killed, but, as we have already seen, the toxin comes from the bacilli, not from decomposition of food as such (in fact, food does not decompose in the absence of germs). Death is common in botulism, but an antitoxin is now available which, if used in time, can cure the disease.

The botulinum toxin, which paralyses muscles, has found some medical uses. "Botox" is being used as a cosmetic treatment injected into the forehead to reduce obvious wrinkles. It may have a more valuable role in overcoming muscle rigidity accompanying a number of medical conditions.

Diseases Caused by Fungi.

Numerous fungi are pathogenic (*i.e.* cause disease), and fungal diseases may be primary or secondary to other diseases; allergies to fungi are also important. The most common fungal disease is candidiasis, which is infection with the imperfect yeast-like fungus *Candida albicans*; this frequently infects the feet (athlete's foot), the mouth and the vagina, producing local itching as the main symptom. Athlete's foot affects one in six people.

Ringworm or **Tinea**, despite its name, is not caused by worms but fungi which cause ring-shaped pigmented patches on the skin, sometimes covered with vesicles or scales.

Actinomycosis, a disease caused by bacteria which superficially resemble fungi, is a serious but treatable condition with inflamed lymph glands around the jaw or ulcerating sores on the skin; it can also affect the lungs, intestines and brain.

The Venereal Diseases.

Sexually transmitted disease (Venereal Disease) is spread by sexual intercourse with an infected person (or with intimate acts associated with it—*e.g.*, "oral sex"). In the last few years in the UK, sexually-transmitted infections have more than doubled, with syphilis and gonorrhoea showing alarming increases.

Promiscuity therefore increases the risk. Not all lesions in, on or around the genitals are necessarily venereal disease. If in doubt consult your own doctor or attend one of the many special clinics which can be found in most cities. Their location is usually widely advertised. Always act promptly.

Gonorrhoea is the result of an infection by the gonococcus (*Neisseria gonorrhoeae*) and ordinarily comes on after an incubation period of three to seven days. However, babies can get an infection of the eyes, known as *ophthalmia neonatorum*, from their mother if she is infected, and gonorrhoea in young children is often the result of being in contact with infected towels or clothes. The disease in adults is evident when there is a thick, creamy discharge from the sexual organs and sometimes pain on passing water; in infants ophthalmia is prevented by the use of silver nitrate eye-drops at birth. Gonorrhoea is fairly easily cured by the use of sulpha drugs or penicillin; but unfortunately venereal disease is increasing and drug-resistant forms are becoming more common. These strains may soon prove impossible to treat effectively with current drugs. Cases of gonorrhoea doubled in England between 2009 and 2015. A large rise is reported in gay and bisexual men. A new drug-resistant strain appeared in 2015, giving doctors great cause for concern about this "supergonorrhoea".

Syphilis is a serious venereal disease caused by a spirochaete (*Treponema pallidum*). Stories about lavatory seats are simply stories, although it is occasionally possible to get syphilis by other than sexual means. But this is very unusual, although kissing can spread the disease. Children, too, can be born with syphilis (the so-called *congenital syphilis*).

Adult syphilis begins with a sore, known as a hard chancre, at the point where the spirochete of syphilis has entered; this may be on the lips, through kissing; on the sexual organs, through intercourse; and very rarely, as explained above, elsewhere. In a short time the chancre disappears and all may seem to be well, but this primary stage is followed by a secondary stage with sore throat, a rash, headache, and enlargement of glands. This, if left alone, also clears up, but is followed by the tertiary stage, in which a chronic infection develops in some part of the body which, presumably, is most susceptible in the particular individual. Thus there may be chronic syphilis of the skin, the bones, the heart, liver, or nervous system.

Syphilis, in common with other sexually-transmitted diseases, is growing fast in Britain. There was a 15-fold rise in syphilis in the UK between 1998 and 2003 and it has continued to rise over the last decade, particularly among gay and bisexual men.

Tabes Dorsalis. In the nervous system, the commonest forms are the two diseases of *tabes dorsalis*, in which the spinal cord is infected, and GPI (general paralysis of the insane), in which the brain and mind are affected.

In congenital syphilis the pregnant mother gives her child syphilis. Such infants are often stillborn or premature, they look wizened, like little old men, and amongst other symptoms are eye disease, "snuffles," a flattened nose, and when the adult teeth appear the front ones may be notched at the biting surface.

It was for syphilis that Ehrlich produced his "magic bullet"—an arsenical drug, known as salvarsan, which could attack the organism selectively without harming the body and was the first of the modern specific drugs. Present-day treatment is with penicillin. GPI was once treated with malarial therapy with some success. Penicillin alone is often adequate.

Chancroid produces small septic ulcers around the sex organs, with swelling of the local glands in the groin, which may suppurate. It is caused by a bacillus, and can usually be cleared up by antibiotics within a week. Scabies and lice often pass from one body to another during sexual intercourse, but are not usually thought of as venereal in origin, although in many cases they are.

Herpes virus infections may be oral ("Cold sores") or genital. These recurrent sores appear particularly at times of physical or emotional stress. They are not curable, but medicines may shorten episodes. Using latex condoms or spermicide may help protect your partner.

HIV/AIDS (*see* **Z11**) may be spread by sexual intercourse, or by blood. The use of condoms reduces the risk of sexual transmission.

Tropical Diseases.

Nothing is more difficult than to define the term "tropical diseases." One might define them as the diseases which occur in tropical climates—but then measles occurs there too; and if they are defined as those diseases which are found *only* in the tropics, the solution is no easier, since leprosy, cholera, smallpox, and typhus are usually listed as tropical diseases, yet were found here until fairly recently—and the odd case still is.

But what a story could be told about the conquest of those infections which were—and many still are—the scourge of humanity! One day when generals and dictators are forgotten we shall remember that great international army of physicians and bacteriologists who have saved millions of lives and infinitely reduced human suffering: Koch and Ehrlich of Germany, Pasteur and Roux of France, Ross and Jenner of Britain, Reed of America, Noguchi of Japan, and many others.

Relapsing Fever, common in India and Africa, may be louse- or tick-borne; the germ is a spirochaete, similar to that of syphilis, but the disease is non-venereal. Relapsing fever gets its name from the fact that the temperature remains high (39° 41°C) for about a week, returns to normal for a week, and rises again. There may be three to five relapses of this sort. Penicillin is effective; lice or ticks must be eradicated.

Leptospirosis (**Weil's disease**), is also caused by a spirochaete, and spread by rats. Now it is rarely found in Europe, although it occurred in the trenches during the First World War, in men working in sewers *etc*.

It is rarely fatal, but leads to high fever and jaundice. Penicillin in high dosage or tetracycline at an early stage is essential.

Yaws is also a spirochaetal disease, common in the tropics and particularly in children. It is unpleasant, but not serious, and tends to clear up in a year or so. There are raspberry-like growths on the skin, which disappear with the drugs used in syphilis (although the condition is non-venereal). The Wassermann reaction, positive to syphilis, is also positive in yaws.

Leprosy. Whereas syphilis, relapsing fever, epidemic jaundice, and yaws are caused by spirochaetes, leprosy is caused by a bacillus resembling the bacillus of tuberculosis. Apart from the difficulty of classification, many popular beliefs about the disease are untrue. It is *not* the oldest disease afflicting man; *not* a disease confined to tropical countries; it is *not* very catching; *not* hereditary, *not* incurable; and the fingers and toes do *not* drop off.

Leprosy is a serious disease not because of disfiguring light-coloured skin patches and lumps, but because it destroys peripheral nerves. Leprosy may disappear spontaneously, or it may progress until the face is lion-like and the hands and feet wasted and ulcerated. The disease rarely kills, but it is the world's greatest crippler. Romania is home to the last leper colony in Europe.

Leprosy was once fairly common in colder Western countries, though its extent was exaggerated. The great majority of the people who suffer from leprosy live in tropical countries. There are around 230,000 new cases annually -60% are in India. Prolonged and intimate contact with an "open" case is said to be the main mode of infection, but only one infected husband in twenty passes leprosy to his wife.

The cheap synthetic drug dapsone is highly effective in leprosy, but problems in delivery to third-world settings has resulted in the emergence of resistant strains, so that much more expensive drugs now have to be used. The WHO has launched an ambitious "multi-drug therapy" programme in an attempt to bring this disease under control.

Established deformity (such as claw hand, drop foot, paralysed eyelids) can be mitigated by reconstructive surgery, although lost sensation cannot be restored.

In 2016 India began testing the world's first leprosy vaccine in its leper colonies across the country.

In the past, some Christian missions were concerned with the plight of the leprosy sufferer. Now, non-sectarian voluntary agencies, Governments and the World Health Organisation have joined in the fight against the disease. Enough is known to control the disease and great efforts are now being made to eradicate it.

Plague is another disease caused by bacteria, common in Europe at one time, but now largely restricted to Asia. Nevertheless, it caused millions of deaths in Europe during the years 1348 49 and 1665 and was the "Black Death," which, indeed, changed the course of history. The full DNA of this was uncovered in 2011.

Plague is carried by the bite of the rat or gerbil flea, but, once people become infected, spread may occur from one to the other by droplet infection—*i.e.*, by coughing and sneezing. After an incubation period of two to ten days, fever develops, rather like severe influenza, and in a day or two the glands in the groin begin to swell, followed perhaps by swelling of the glands elsewhere.

Of this usual glandular type (bubonic plague) half of untreated patients die, but if rapidly treated cure is usual. It is also possible to get disease of the lungs from droplet infection and blood-poisoning from infection of the blood-stream. Both the latter types are almost invariably fatal.

Short courses of antibiotics protect contacts. Vaccination is available but usually not used.

Protozoal Diseases.

Nearly all the diseases caused by protozoa are tropical diseases, although one of the best-known protozoans is the harmless amoeba found in British ponds. Protozoal diseases are caused by these organisms, large in comparison with bacteria, which should really be thought of as one-celled animals. Viruses are neither animals nor plants, are much smaller than the other two groups, and have some distinctive characteristics described elsewhere.

Among the diseases caused by protozoa are sleeping sickness or trypanosomiasis, malaria, and amoebic dysentery (as contrasted with bacillary dysentery), another disease, leishmaniasis—also known by the numerous names of kala-azar, dumdum fever, and, in milder form, Delhi boil, Oriental sore, or Baghdad sore—will also be mentioned briefly. More recently, humans have been affected by *cryptosporidosis*. This is an intestinal infection usually passed to humans from farm animals (*e.g.* by infected milk). Symptoms include severe diarrhoea. These infections are few, but important in their influence on man; until recently malaria was responsible for one-fifth of all human sickness, sleeping sickness not so long ago caused a large part of Central Africa to be uninhabitable, and in some areas of the tropics there are probably more people with, than without, amoebic dysentery.

Malaria. The word, of course, means "bad air." When it was formerly found in Britain it was known as *ague*. Yet, although malaria and "bad air" may often go together, and influenza and cold, it does not follow that bad air (whatever that may be) causes malaria nor that cold causes influenza. In fact, the Anopheles mosquito carries the amoeba of malaria, and the mosquito prefers climates which some people might describe as "bad," but it is the amoeba, not the air, which causes the disease. Anyhow, the unfortunate mosquito might well use the phrase honoured by many generations of schoolmasters: "It hurts me more than it hurts you!" For the mosquito, too, is sick, and passes on its sickness to the person it bites.

There are several types of plasmodium—which is the scientific name for this amoeba—producing attacks of fever varying in severity and frequency: benign tertian, quartan, and malignant quartan. Entering the body from the mosquito bite, the parasites penetrate the blood cells, multiply there, and finally burst into the blood stream. When this happens the temperature rises, and then they return to the cells to carry out once more the same procedure. Depending on the type, the attacks of fever may be at intervals of two or three days, severe or milder. When someone with malaria is bitten by a mosquito the infection can be transmitted to the next person it meets, but malaria is not infectious from one person to another directly.

Treatment of Malaria. Quinine, of course, is the time-honoured remedy, but many other drugs are now available: mepacrine, primaquine, chloroquine and some sulpha drugs. The drug must be taken long enough for the infection to die out, otherwise relapses can occur even after leaving a malarial country. Trials of a ground-breaking new vaccine during 2013 have been very exciting. It marks a milestone in the fight against a disease affecting 250 million people each year (90 per cent in Africa). Six hundred thousand people (mainly in Africa) die annually from malaria, mainly children under 5 (it is estimated that one child dies every 45 seconds from the disease). Malaria has killed more people than any other disease in history.

The disease now accounts for around 40% of public health spending in sub-Saharan Africa. New drug-resistant strains of malaria are emerging in South-East Asia. And mosquitoes are breeding in increasing numbers in the UK.

Important as are the drugs used in the treatment of malaria, even more so is the control of the parasite-bearing mosquito. The eggs of mosquitoes hatch in water, and there the young or larval forms can be attacked by pouring oil on the surface of pools so that they are unable to breathe, or by introducing small fish which have a partiality for them. Adult mosquitoes can be killed by insecticides or kept away by repellent creams or nets over beds. Prophylaxis with antimalaria before entering and while living in known malarial zones is important.

Today, many British holidaymakers are now contracting malaria, partly as the result of the emergence of drug-resistant strains of the disease. Over 2,000 British travellers a year contract malaria and ten die. Do contact your doctor and take precautions. There are a variety of antimalarials available, so your GP can advise you.

Blackwater Fever is a sequel to malaria in tropical Africa and some parts of India. Rather illogically, it is described as "Blackwater," although the urine is red and the skin is yellow but the result is due to breaking down of the red blood cells by some malarial toxin. Possibly too much quinine may help in producing the illness. Treatment is to give plenty of fluids and no quinine or any other anti-malarial drugs in the early stages. The death-rate is about 25 per cent.

Trypanosomiasis (Sleeping Sickness) is essentially an African disease (although also found in tropical America) spread by the tsetse fly. Its cause is the type of protozoan known as a trypanosome, almond-shaped with vibrating membranes at the sides which enable it to move through the bloodstream, rather like a flat fish in the water.

There are three stages of the disease: first, the stage of fever with enlarged glands and a rapid pulse; which may continue off and on for three years; secondly, the stage of trembling hands, legs, and tongue, vacant expression, and slow and stumbling speech; thirdly, and lastly, the stage of low temperature, apathy (a zombie-like state), wasting of the muscles, and possibly death.

Treatment is with pentamidine, suramin or melarsoprol—which give good results in early cases. Preventive measures in infected areas include the destruction of tsetse flies by insecticide, the cutting down of forests near rivers which are inhabited by tsetse flies, and some authorities have suggested the shooting of big game which may form a "reservoir" of the parasities, whence tsetse flies can carry them to human beings. For similar reasons infected people should not be allowed to move to noninfected areas. Around 6,000 people die of this disease in sub-Saharan Africa each year.

Amoebic Dysentery, also known as *Amoebiasis*, is caused by the *Entamoeba histolytica*, an amoeba whose cysts are found in food and water, or spread by infected fingers or flies. There is mild fever and diarrhoea which contains blood. The disease may become chronic, and can cause abscesses, usually in the liver but sometimes in the lungs. Amoebiasis is treated with chloroquine or nitroimidazoles.

Leishmaniasis, Kala-azar, or **Dum-Dum Fever**, is another amoebic disease, usually spread in this instance by the bite of sandflies. It is also known as tropical splenomegaly—enlargement of the spleen in ordinary language—since infection results in enlargement of the spleen and liver, low, irregular fever, and death within a year or so. A milder form, affecting the skin, does not lead to kala-azar, and is fairly readily cured. The cure for both conditions is to give injections of antimony.compounds which reduce the death-rate from kala-azar from 80 per cent, to 5 per cent (but left untreated, the disease is fatal).

Diseases Caused by Parasitic Worms.

Many types of worms infest human beings and other animals. They are interesting for such reasons as their size (which may range from the almost invisible to 9 m or more), their life histories, and their serious or trivial consequences on their hosts. We shall mention only a few groups here, and mainly the ones likely to be met with in Europe—the tapeworms, the roundworms, and the threadworms—although some tropical types will be described briefly.

Tapeworms, as we have seen earlier, like many other types of intestinal worm, lead a double life. What usually happens is that the worm breeds in the human intestine, the eggs pass out in the faeces, and are then swallowed by animals eating contaminated material. In the animal the eggs hatch out into larvae—primitive forms which penetrate the muscle, forming cysts—and man is infected in turn by eating its meat. Thus *Taenia solium* gets into the flesh of pigs, which, if imperfectly cooked (measly pork), causes infestation of the intestine in man. It reaches a length of about 3 m. *Taenia saginata*, which reaches a length of about 6 m, is spread in imperfectly cooked beef, and in Baltic countries *Dibothriocephalus latus* gets into the human intestine from caviar or undercooked fish. It reaches the awesome length of 9 m.

Now all the worms we have mentioned so far are found in the human intestine, and the cysts, which are much more dangerous and unpleasant, in the animal's muscles. But in some worms the reverse happens, with the adult in the animal's intestines and the cysts in man. Thus in Australia the dog tapeworm (*Taenia echinococcus*) produces cysts in both sheep and man. This is known as *hydatid disease*, and may remain unsuspected until cysts in the lungs, liver, or elsewhere become infected or rupture. *Trichinella spiralis* is similar in action, being found in the intestines of pigs and getting into the muscles or other organs of man. The main difference is that this worm migrates from the pig's intestines into its muscles, whence it reaches man in undercooked pork meat or sausages. The muscular cysts cause swellings and sometimes pain. There are changes in the blood, swelling of the face and leg in the early stages, and fever. *Taenia echinococcus* and *Trichinella spiralis* are small not more than 0·5 cm in length—but are more serious in their consequences than the large worms. Treatment is very difficult, and ordinarily all that can be done is to deal with individual cysts when they make themselves apparent.

The large tapeworms, *Taenia solium* and *saginata* and *Dibothriocephalus latus*, produce varying symptoms or none at all. Usually they are not discovered until some segments of the worm are excreted, but there may be mild indigestion, excessive hunger, and occasionally anaemia. However, when the worm is discovered the patient, not unnaturally, is likely to become anxious and uncomfortable at the thought of "having" a tapeworm; these symptoms are caused by the worry rather than the worm.

Treatment is, of course, a matter for a doctor, who now has a number of very effective drugs to choose from. One has to make sure that the head of the worm has been removed, otherwise it will continue to grow.

Roundworms are similar both in appearance and size to ordinary earth-worms and the eggs reach man, not from an animal, but from the contaminated fingers of someone else who handles food. They usually give rise to no symptoms, and are noticed only when discharged in the faeces or occasionally vomited up. Piperazine is an effective treatment. It is now known that King Richard III suffered from roundworms.

Threadworms, as the name suggests, are like small 0·5–1 cm long pieces of white thread. They are very common in children, and live mainly in the caecum *i.e.*, the part of the large intestine near the appendix. The males, which are the smaller ones, remain there, but the females pass down towards the rectum at night-time and lay their eggs in the area around the anus. Infection is by contaminated hands handling food—especially uncooked food—and water. Threadworms are not serious, and cause few symptoms other than itching around the anus and between the legs, but heavily infected children may show symptoms of anaemia. The nervousness often shown by such children is usually the result of the irritation produced by the worms in the anal region. Infection is not common in adults, and in children tends to disappear at puberty.

Treatment is, in theory, simple; for the worms are easily destroyed by a number of drugs, such as piperazine and other, more modern drugs. Ointment is applied to the itching area, and the child should be prevented from scratching. However, since the eggs may lie about the house for some time, reinfection often happens, especially if there are several small children in the home who may pass the disease from one to another.

The idea that intestinal worms in general are likely to cause loss of weight by absorbing food eaten by the patient is largely mistaken; for although it is true that they do live on this food, the amount taken is not enough to be significant.

Tropical Worms. *Bilharzia* has been mentioned before in connection with its frequency in Egypt, although it is also found in other parts of Africa and the Middle East. Overall, around 90% of cases are found in Africa. There are two main types: one infecting the bladder (*Schistosoma haematobium*), the other the rectum (*Schistosoma mansoni*). *Bilharzia* is more correctly known as *schistosomiasis* and seems to affect children most.

The parasite's fantastic life-history begins when people bathe in infected water, and the small swimming forms known as cercariae pierce and enter the skin—or they may enter the body by drinking infected water. From the skin they pass to the portal vein below the liver, remain there six weeks until they become adult and then swim against the blood-stream down to the pelvis, where the female lays eggs which have a sharp spine.

The parasitic eggs penetrate into the bladder or rectum depending on the type of fluke—and pass out in the faeces or urine. If they enter water they hatch out into small moving forms which seek out a water-snail, develop further in its body, and leave it in the form of cercariae ready to find a new human victim. The female fluke is slender and round, about 2·5 cm in length, the male, flat and leaf-shaped, is about 2 cm long, and, as we have seen, their grisly courting takes place in the portal vein, whence the impregnated female passes to the bladder (*haematobium*) or rectum (*mansoni*) to lay her eggs.

Infection results in raised temperature and, in the urinary type, blood in the urine; in the intestinal type blood is found in the faeces, and there are symptoms resembling dysentery – *e.g.*, diarrhoea. Treatment in both cases is with drugs. Needless to say, attempts should be made at prevention by telling people to avoid infected canals (usually easier said than done), and by periodically cutting off the water supply to the canals to kill the snails.

Hookworm Disease, or ankylostomiasis, is found in many parts of the world, especially in miners who work on damp ground. The tiny worm enters the body usually through the feet, passes through the blood-stream to the lungs, eats through into one of the bronchial tubes, climbs the windpipe, and passes down the oesophagus into the stomach to end up in the duodenum. It causes anaemia, can be fairly readily cured, but is occasionally fatal.

Elephantiasis. Some types of parasitic worm are spread by insects. Thus in *Filiarisis* mosquitoes inject by their bites the infantile forms of a tiny worm which enters the lymphatic channels; there the blockade they cause leads to the swelling of the legs and the lower part of the body with fluid (known as elephantiasis). An animal pill is to be given out in India, where 40 million people suffer this debilitating illness.

PHYSICAL INJURIES AND FIRST AID.

This section which lists emergencies in alphabetical order is designed for rapid reference. Yet it would be wise to make sure now of knowing very thoroughly the parts dealing with bleeding, burns, resuscitation, shock and unconsciousness, situations which are immediately life threatening.

Nothing can teach first aid as effectively as attending one of the many courses organised by the three main organisations:

St. John Ambulance Association, 1, 63, York Street, London WIH IPS. *See also* **Z23**.

British Red Cross Society, UK Office, 44 Moorfields, London EC2Y 9AL (www.redcross.org.uk).

St. Andrew's Ambulance Association, Milton Street, Glasgow, C4.

Their local addresses are available on the Internet or in the telephone directory; enquiry will get details of classes held at various hours of the day.

Purpose of First Aid.

First aid is not treatment proper (which is "Second Aid"). It aims to save life, to prevent further harm or suffering and to keep the victim in the best condition until taken over by a doctor or a nurse.

Under ordinary circumstances attempts to do more can be detrimental. If you limit your help to what is outlined here you cannot go wrong.

General Principles.

There are two priorities:

1. That the patient must breathe.
   (—*see* **Choking, Resuscitation, Unconsciousness**)
2. That severe bleeding is controlled.
   (—*see* **Bleeding**)

In any accident scene try to judge quickly which person most needs immediate attention. Treat a victim where he or she is; do not move him or her unless the surroundings suggest immediate danger (*e.g.*, fire, fumes, collapsing building).

Handle the patient with gentleness and sympathy yet achieve an atmosphere of reassurance and confidence by firm instructions and methodical actions.

Clear away a crowd (always demoralising to the victim) and use likely bystanders to telephone for an ambulance when necessary. Let your message be clear and written if possible. Let it clearly state the exact locality, the number of patients and the nature of their troubles. Always guard against shock (*q.v.*).

Asthma Attacks.

Breathing becomes very difficult, harsh and wheezing, fighting against air passages narrowed in spasm. Fear aggravates and relaxation relieves spasm. Show calm confidence.

1. Allow fresh air ventilation. Loosen tight clothes.
2. Help the mechanics of breathing by telling the patient
   to sit upright with a straight back but all the rest of the body relaxed;
   to direct breathing movements from the lower part of the chest.
3. Give the patient medicines already prescribed for the emergency but avoid overdose.

Bleeding.

Treat mild bleeding as for wounds (*q.v.*).

For severe bleeding aim to let the blood clot by stopping or slowing the flow.

1. Immediately firmly press the edges of the wound together between fingers and thumb or press the palm of the hand hard down on it. (Maintain this at least ten minutes.)
2. Lie the patient down: elevate a bleeding limb (unless you suspect it to be fractured).
3. Slip a thick pad (handkerchief, gauze, wool) under your hand. Replace the hand pressure with a firmly bound bandage (stocking, belt, scarf).
4. If blood still leaks out add another pad and bandage.
5. Protect against shock (*q.v.*).

Nose Bleeding.

1. Have the patient sit up.
2. Get him or her to pinch between finger and thumb the whole lower half of the nose and maintain this for at least ten minutes. Repeat another ten minutes if necessary.
3. Tell him or her not to sniff or blow his nose.

Ear Bleeding.

1. Bandage or tape a loosely covering dressing (gauze, handkerchief) over the ear.
2. Lie the patient down towards the injured side.—*Nose or ear bleeding which follows a blow to the head may signify a fractured skull which needs immediate medical attention.*

Tooth Socket Bleeding.

This may follow after a dental extraction. Get the patient to bite hard on to a big pad (gauze, bunched-up handkerchief) placed over the bleeding area. He or she maintains pressure at least ten minutes sitting with a hand under the chin and the elbow on a table.

Blood Vomited.

This could appear black due to the effect of stomach acids.

1. Lie the patient down, on his or her side, with the head low.
2. Give him or her nothing to eat or drink.
3. Get a doctor or ambulance.
4. Guard against shock (*q.v.*).

Blood Coughed Up (*see also* Chest Injury).
Blood from the Back Passage.
Blood in the Urine.

However slight and brief the loss, always seek a doctor's opinion.

Blisters.

Leave them intact and protect them with a simple dressing. But if they are so big as to be in the way and need flattening:—

1. Boil a needle for ten minutes: leave it in the water until needed.
2. Wash the blister area with soap and water.
3. Holding the needle by one end pierce the blister at two opposite points. Press down with clean cloth to squeeze the fluid out.
4. Dress it like a wound (*q.v.*).

Burns (*see also* **Chemical Burns**).

1. Put out flames the quickest way: a douche of water; smothering with cloth (rug, coat, blanket).
2. Remove burnt clothes, but leave on what is adherent to the skin.
3. Cool the burnt part with cold water for at least ten minutes, longer if pain persists. Plunge a limb in a bucket or sink. Cover other parts with a thick cloth soaked in water; renew it if it dries.
4. Lie the patient down; keep a burnt limb elevated; remove possibly constricting things (rings, bracelets) from a burnt region before it swells.
5. Dress the burn as a wound (*q.v.*).
6. Guard against shock (*q.v.*)—in severe burns give to drink half a cupful of tepid water with a pinch of salt and sugar every ten or fifteen minutes.

Car Accidents.

1. Urgently stop severe bleeding (*q.v.*) or give resuscitation (*q.v.*) where this is needed; treat choking (*q.v.*). Unless they are at risk from fire or fumes leave the injured where they are. Look for victims thrown into ditches or over walls and hedges.
2. Minimise risks by forbidding smoking (petrol leak), by switching off the ignition and applying the brakes.
3. Set your own car off the road if possible; at night have its light shining on the scene.
4. Detail bystanders (wearing or carrying white objects at night) to stop approaching traffic on either side.
5. Send a message for help, detailing the exact place, the number injured and the injuries.
6. Give other first aid to those in the cars without trying to move them: attempts to pull them out, especially from a distorted car, can do great harm. Leave to the rescue services.

Chemical Burns.

Rapidly wash away the chemical with copious free-flowing water. Remove any contaminated clothing.

The contaminated eye, closed in painful spasm, may need gently forcing open; let the water flow on it without force and bend the patient towards the affected side so that the washings flow off at once.

Chest Injury.

Where there has been a severe blow or deep wound to the chest, possibly followed by blood being coughed up:

1. Clear the mouth of any obstruction (blood, vomit, dentures).
2. If there is an open wound at once close it with the palm of your hand firmly applied. While you keep it there, improvise a thick pad

(towel, cloth, handkerchief, sock) to replace your hand. Tape or bandage it securely to make an air-tight seal.

3. Loosen tight clothing.
4. Lie the patient down *towards* the injured side. If he or she has difficulty in breathing have him or her half propped up with head and shoulders raised.
5. Cover the patient loosely.
6. Get ambulance urgently.

Choking.

1. With your fingers try to clear any obstruction (food, toy, dentures) from the back of the throat.
2. If this fails tell the patient to relax, to bend well forward; give a hard slap between the shoulder blades. This may loosen the obstruction so that the patient can cough it out. A small child you place head down over your arm or your bent knee. Try up to four separate slaps.

If back slapping fails try to force the matter out by pressure:

1. Patient standing: stand behind him; put both your arms round his waist. Patient lying: turn him on his back; kneel astride him.
2. Place your fist (thumb side first) on his abdomen *between his navel and the lower end of his breast bone*; cover your fist with your other hand.
3. Make firm thrust inwards and upwards. This may propel the obstruction out of his windpipe. Try up to four separate thrusts. If these fail continue alternating four slaps and four thrusts. After each of these be ready to remove immediately any matter propelled into the mouth.

After receiving thrusts the patient must be checked by a doctor lest internal damage has occured.

If an obstruction is not cleared and the patient ceases breathing and collapses begin resuscitation.

Always remember that in the unconscious the tongue may fall back and be an obstruction. *See* **Unconsciousness**.

Cold Effects. *See* **Exposure and Hypothermia.**

Cramp.

Cramps may follow severe loss of body fluid and minerals—as with severe repeated diarrhoea, vomiting or sweating. Slowly give tepid drinks containing a small pinch of table salt to each cupful or with diluted meat or yeast extracts.

Sudden cramp in a single muscle can be stopped by having the patient strongly stretch the muscle. In the front of the arm; straighten the elbow and swing the arm back. In the front of the thigh bend the knee and swing the leg back. In the back of the thigh: straighten the knee and swing the leg forward. In the calf: bend the foot up at the ankle while straightening the leg.

Diabetes.

Under certain circumstances a diabetic treated with insulin may suddenly collapse through sugar deficiency. Passing through phases of weakness, vagueness, sweating, tremor, uncoordinated actions and slurred speech he or she may go into a coma.

If he or she is conscious give him two teaspoonfuls (or lumps) of glucose or sugar in water. Failing this, give anything sweet; jam, honey, chocolate. This should clear him rapidly but repeat the dose after ten minutes.

If he or she is unconscious send for medical help urgently. Give nothing by mouth and put the patient in the recovery position (*q.v.*).

Ear—object in.

Do not try to poke it out.

A small object (*e.g.*, insect) can sometimes be floated up and out by lying the patient down with the ear uppermost and pouring in a little water or olive oil. But do not try this if the ear drum is possibly damaged or the ear is painful.

Electric Shock.

At once disconnect the current (at the switch or by pulling a plug out). If you cannot do this do not touch the patient but knock him away from his contact with dry non-conducting material; wooden stick, light furniture, folded thick garment.

He may need resuscitation (*q.v.*). He may have sustained a fracture (*q.v.*) or a burn. He may recover, only to collapse later; keep watch and send him to hospital.

Beware of very high voltage currents, as from wires of electric pylons: keep at least 20 feet away and do not try to rescue until the electricity authority has cut the current.

Epileptic Attack.

The patient may suddenly become unconscious, fall and soon begin convulsive jerkings, and sometimes frothing at the mouth.

1. Do not try to stop the jerking, but protect him from banging against furniture. Move the furniture or push cloth in position as buffer.
2. Clear froth from the mouth.
3. Once the convulsions stop put him in the recovery position (*q.v.*)—but beware lest he sustained a fracture (*q.v.*) in falling.

A succession of closely following attacks is dangerous: get medical aid at once.

Exposure.

A hill climber or a worker inadequately dressed against cold weather becomes slow, inefficient, clumsy, drowsy. Eventually he or she collapses and if not properly treated may die.

1. Put the casualty to rest.
2. If you can, get him or her into a warm shelter. Otherwise protect him with screens of clothes or blankets and poles.
3. If he or she is conscious give warm drinks (cocoa, chocolate, tea). On no account give alcohol.
4. Get wet cold clothes off if possible and put casualty in warm dry covers (sleeping bag, blankets). A plastic sheet over those helps to retain heat. Include the head, leaving only the face free. Well-prepared walkers will equip themselves with a special survival bag, now widely available.

Gradual rewarming is given when the patient has become cold gradually. When exposure has been sudden, as with falling in extremely cold water, you can warm up the patient fast in a bath at about 40° C. (103° F.).

Eye Injury.

Fix a loosely covering pad over the eye and get medical aid.—Do *not* use drops or ointments.—If the wound is severe and painful keep the patient on his back and cover both eyes (since movement of the good eye entails that of the injured one).

Eye—Object In.

Have the patient seated in a good light and stand behind him or her. If you can see the object on the white of the eye try to lift it off gently with the rolled-up and moistened twist of a handkerchief. If it does not come easily it may be embedded; leave it alone.

If it is within the coloured part of the eye leave it for a doctor to treat.

If you cannot see it look under the lids. The lower lid you pull down as he or she looks upwards. The upper lid you must evert as he or she looks down; lay a matchstick along the "hinge" of the lid; firmly grasp the edge of the lid and roll it up over the matchstick.

Fainting.

Lie the patient down with his legs higher than his head (if this is not possible, get him seated with his head bent low between his knees); loosen any tight clothes: tell him to breathe deeply and slowly. He should soon recover. A drink of water (provided he is conscious) will help. If he has fainted fully treat as for unconsciousness (*q.v.*).

Fractures.

Always suspect a broken bone where a blow or crush near a bone is followed by pain, swelling, deformity, weakened or restricted movement. Not all these features are always present: sometimes relatively slight pain is the only one.

Your task is to prevent movement which could worsen the condition by shifting a broken edge of bone into an important organ, or by making it pierce hitherto unbroken skin (with a risk of infection). No one will blame you for undue caution—but all will hold you responsible if you allow a fractured bone to do more damage by movement which could have been avoided.

When a fracture is suspected:—

1. Warn the patient not to move and bystanders not to try to lift him or her.
2. At once control any severe bleeding (*q.v.*). Dress any wound (*q.v.*) temporarily.
3. Now immobilise the fractured area including the joint at either end. The best splint is the patient's own body; *e.g.*, injured arm secured against chest, injured leg against good leg (move the good leg up to the injured one). Or a thin board or rolled-up newspaper, well buffered with cloths and towels tied round it can be slipped under a fore-arm and wrist. Between the injured part and the splinting surface fill any hollows with firm padding of wool, or bunched-up cloth, socks, handkerchiefs. Tie the whole firmly with bandages (or stocking, thin towels) making the knots over the splint (not the hurt part) and avoiding bandage directly over the level at which you suspect the fracture. Work gently; do not lift or move the injured part.
4. Help to reduce shock (*q.v.*).

If you expect expert help (doctor, nurse, ambulance) to arrive soon, then omit step 3 above.

The fractured spine. When a blow or fall gives a painful back or neck, the vertebral column may be fractured. Inexpert moving may possibly drive a bone fragment into the spinal cord of nerves, causing paralysis or loss of feeling. It is most important to let the patient lie still until experienced first aiders take over. Keep the patient warm.

Frostbite.

Do not heat the area directly or put it in hot water. Do not rub it.

1. Remove any wet cover (*e.g.*, glove).
2. Remove any tight object (garter, ring, *etc.*).
3. Cover the area loosely with dry material and let it warm up slowly. Fingers can be tucked under clothes into the opposite armpit. Nose, chin or ear can be covered with a dry hand.

Hanging.

Support the victim by the legs. Get the cord cut and be prepared to receive his or her weight as the person falls. Loosen the cord round the neck. Act fast. Get medical help.

See also **Choking** *and* **Resuscitation.**

Head Injuries.

Blows to the head can cause fracture of the skull and also brain damage.

Fracture of the skull is not always obvious. Skin may swell over the site. Sometimes a fracture of the base of the skull (the body platform within the head at eye and ear level which supports the brain) may show up by bruising round an eye or by blood loss from ear or nose (*see* **Bleeding**).

Brain Damage may be of two kinds:—

Concussion, a temporary "shaking up" of brain tissue causing immediate "knock-out" unconsciousness. Recovery is in anything from a few seconds to several hours.

Compression of the brain develops from bleeding within the skull, from displacement of a fractured bone or from general swelling of the damaged brain tissues within the hard unyielding skull. The patient gradually (minutes or hours) becomes comatose and perhaps unconscious. This condition is dangerous.

The patient is unconscious—see unconsciousness.

The patient is dazed: put him in the recovery position (*q.v.*) and watch him closely until help comes.

The patient recovers after a knock-out (concussion). He may yet develop features of compression as well. However much he wants to carry on, keep him at rest, under observation and get medical advice.

In all cases remember that head injuries are often accompanied by injuries to other parts of the body.

Heart Attack.

Sudden heart attacks may produce:—

severe gripping pain in the centre of the chest, sometimes spreading to the neck, shoulder or arm; fast weak pulse; breathlessness; pallor and blueness; sweating.

or sudden painless breathlessness with slight cough and very wet bubbly breathing.

In either case send urgently for medical help. Get the patient to rest (in bed if possible). If he or she is very breathless it will be easier for him or her to be in a sitting position, against banked-up pillows. Otherwise have the patient laying down.

Loosen tight clothes. Keep the patient warmly but loosely covered. Mop any sweat from the face.

Heat Effects.

Heat Exhaustion. Anyone working in an unusually hot atmosphere is helped to remain cool by copious sweating which extracts heat from the body as it evaporates off the skin. But this loss of fluid also carries with it essential minerals from the body. The patient may collapse with his temperature normal or just a little raised; his skin is pale, moist and sunken, his pulse fast and weak. Muscles depleted of minerals go into cramp.

Let him rest in a cool place and give him (slowly) fruit juices or water with half a teaspoonful of salt added to each pint.

Heat Stroke happens in unusually hot and moist areas in rare industrial circumstances and in some tropical zones. Evaporation of sweat cannot take place in an atmosphere already saturated with water vapour. The patient becomes burning hot with a red dry skin and a fast forceful pulse. He may suddenly collapse and go into coma.

He must rest, have his clothes removed and be fanned or sponged down with cold (but not iced) water. The condition is dangerous and needs medical help.

Hypothermia.

Small babies and the elderly are specially susceptible to cold, *e.g.*, overnight in a poorly heated bedroom. They become lethargic, comatose and then unconscious. Extremely cold to touch, even under bedclothes, the skin is white (though in babies it may be deceptively pink). Death may follow.

Cover the patient well including the head, leaving the face free. Then put in the recovery position (*q.v.*). Warm him GRADUALLY by warming the whole room and by giving slowly warm (not hot) drinks. Do NOT give alcohol. Do NOT use electric blankets or hot- water bottles.

Hyperthermia is the opposite of hypothermia.

Insect Bites.

Cool with water or (better) smooth in antihistamine cream.

If a bee sting has been left in the skin pull it out with fine tweezers: apply these well down near the skin so that they do not squeeze in any venom left at the free top of the sting.

Lightning.

As for electric shock (*q.v.*) except that the patient can be touched at once as he bears no electric charge. Put a dry dressing over any skin burns.

Nose Bleed. *See* Bleeding.

Nose—Object in.

Do not try to probe it. Unless GENTLE nose blowing gets it out consult a doctor.

Poisoning.

Do not try to administer antidotes. Do not give salt solutions.

If the patient is unconscious.

Treat as for unconsciousness (*q.v.*).

If he is conscious.

Give, slowly, soothing drinks to dilute the poison (water, barley water, milk and water).

Put him or her in the recovery position (*q.v.*) while awaiting the ambulance. He or she may lose consciousness.

In all cases.

Get the patient urgently to hospital.

Send with him or her any remaining poison or empty container and a sample of any vomit.

Keep a close watch all the time you are with the patient.

Poisoning by pesticides (weed or insect killers).

The patient must be at complete rest. If the clothes and skin are contaminated with the poison (splashes, spray droplets) remove clothes and wash the skin copiously with water (avoid contaminating yourself). If he or she is conscious give sweetened drinks.

Poisoning by gases.

Get the victim rapidly out of the contaminated atmosphere, but do not venture within this unless you have a lifeline and respirator, with others to safeguard you.

Recovery Position.

This safeguards the patient's comfort and breathing if he is unconscious, or comatose, or likely to lose consciousness. It consists in having him or her—

laying on his or her side;
with lower arm and leg stretched out straight behind;
upper leg and arm bent forward at right angles at hip, knee, shoulder, elbow;
face tilted slightly downwards and head bent backwards (NO pillow).

This ensures a clear airway and lets any fluid in the mouth (saliva, blood, vomit) flow out and not choke the patient.

To get him or her in position:

1. Empty the pockets; remove items like bracelet or wrist watch. Put the belongings away safely. Loosen tight clothing.
2. Kneel alongside him or her.
3. Straighten the arms alongside the body; tuck the nearer hand below the hip.
4. Put one of your hands under the face to protect it as your other hand pulls them at the hip over towards you, on his or her side.
5. Adjust the limbs.
6. Cover with a blanket or coat.

However, do not move the patient if circumstances suggest he or she received a heavy blow to the backbone. In that case ensure free breathing by keeping the head bent well back (never sideways). Be ready to clear immediately any vomit from his mouth.

Resuscitation.

This is the attempt to restore life to someone who has stopped breathing. NEVER try it unless this really is the case; you will do harm if the patient has collapsed but is still breathing. Do not try it if the problem is that of fighting against choking (*q.v.*).

In cases of drowning do not try to tip the patient up to drain out water; this wastes valuable time.

(It is best to have learnt the technique in organised first aid classes, practising only on a manikin.)

Artificial Respiration.

Act very quickly: –

1. Get the patient on his back.
2. Bend his head fully backwards and keep it thus all the time.
3. With fingers rapidly clear out any obstructing matter from mouth and throat.
4. Hold the mouth open (keep your fingers clear of the lips) and pinch the nose shut.
5. Take a deep breath in: open your mouth wide and seal your lips round his or her mouth: breathe firmly into his or her mouth. The air going in should make the chest rise. Do not blow more forcibly than is needed to achieve this.
6. Lift your mouth off. The chest will now sink as air comes out. Meantime you take another breath in.
7. Continue by repeating the breathing processes of steps 5 and 6.

The first four breaths you give quickly. Thereafter time yourself by the rise and the natural fall of the patient's chest.

With small children you need not pinch the nose, but let your mouth seal over both the nose and mouth of the patient. Much gentler blowing is needed, and quite small puffs are right for babies.

Keep on until medical authority takes over.

If patient vomits turn his head to one side and clear out the mouth. Then resume artificial respiration, with the first four breaths quick ones.

Successful artificial respiration should soon improve the patient's colour, and later you may find he begins to breathe for himself, even if only weakly. Watch this closely, for he may cease again.

Heart Compression.

If there is no improvement it may be necessary to add heart compression to artificial respiration. This, however, cannot be safely learnt except from first aid class teaching and demonstration. (See the Introduction to this section.)

Shock.

Failure of the heart and of the circulation of the blood may follow any serious injury (bleeding, wounds, burns, fractures). This can happen in minutes or hours according to the severity of the lesion.

In first aid terms this dangerous physical condition is called Shock. The patient is pale, cold, sweating, faint or comatose, with weak and fast pulse and breathing.

Try to prevent or to minimise the development of shock before it appears by applying the following simple but valuable measures to every badly hurt patient.

1. At once stop severe bleeding (*q.v.*).
2. Treat the patient where he or she is (unless you both are in an area of danger).
3. Lie the patient down: keep the head low and legs raised (but avoid movement where a fracture is suspected).
4. Loosen tight clothing.
5. Keep the patient warm by covering below and loosely above him or her —but do not use hotwater bottles.
6. Gently dress any wounds—with the minimum of disturbance.
7. Guard the patient's mental state. Be sympathetic but as optimistically reassuring as possible. Never whisper to others. Never assume that because the patient appears unconscious he or she cannot hear and understand what is said.

Do not give the badly injured patient anything to drink. This could worsen his condition and risk vomiting and choking, especially if he becomes unconscious or needs an anaesthetic. If he is very thirsty let him refresh himself by sucking a moistened handkerchief.

Snake Bite.

The adder is the only dangerous snake in Britain. Its bite can cause collapse and great pain, but only very rarely is it fatal.

1. Lie the patient down.
2. Wipe or wash the bite area. Put on a dry dressing.
3. Cover the area with a thick pad and bandage it in position so that it presses down very firmly.

4. Immobilise the bitten part as if it were a fracture (*q.v.*).
5. Get the patient rapidly to hospital.
6. Reassure him about his recovery. Give aspirin or paracetamol to minimise pain.

You NEVER cut or suck the bite, or apply chemicals. You NEVER use a tourniquet.

Sprains.

These are stretched and torn ligaments at a joint. Immediately after it happens you can reduce the swelling and pain which will follow by applying a cold compress—a cloth soaked in cold water and then wrung out to be just moist. Keep it in position half an hour, and renew it if it gets dry.

Otherwise support the joint firmly with layers of cotton wool interleaved between turns of crepe bandaging. Beware of making it so tight that it interferes with circulation in the limb.

A severe sprain may be difficult to distinguish from a fracture. If in doubt treat as for the latter.

Strains.

A strain is an overstretching of muscle fibres, and is very like a sprain except that it does not necessarily happen at a joint. Treat it as a sprain.

Strokes.

Some part of the brain has sudden damage of its blood supply. The results are as variable as are the functions of the brain: *e.g.*, poor feeling or power in hand, arm or leg, altered speech, loss of bladder control, paralysis of one side, or unconsciousness.

A temporary stroke-like effect (a *"transient ischaemic attack"*) may be the forerunner of more serious damage. Get the patient to bed, if necessary in the recovery position, and keep under observation until the doctor arrives.

Unconsciousness.

In first aid finding the cause of unconsciousness is less important than protecting the patient's breathing. The unconscious patient lying on his back and with head straight or bent towards the chest is at risk of choking from his lax tongue, flopping against and obstructing his throat. Correct positioning prevents this. Act methodically:—

1. Has the patient stopped breathing? He or she will urgently need resuscitation (*q.v.*).
2. Is the airway blocked making breathing difficult? Clear any material from the mouth. Bend the head straight back at the neck (but do not twist or turn it), and keep it there (*see* Choking).
3. Arrest any severe bleeding (*q.v.*).
4. Dress any wounds (*q.v.*).
5. Consider the possibilities of fractures (*q.v.*). If you suspect they might be present do not move him (specially important if he might have injured the backbone); stay by his head to ensure its proper position and to clear out immediately any fluid (saliva, blood, vomit) which threatens to choke.

If the patient can be moved:—

6. Turn into the recovery position (*q.v.*)

Two other important points are that you NEVER try to give anything by mouth to the unconscious or comatose, and that you realise how much you must guard your speech, since these patients may overhear what is spoken near them.

Wounds.

The general treatment is simple, and should avoid the use of antiseptics or ointments.

1. At once control any severe bleeding (*q.v.*).
2. Sit or lay the patient down.
3. Put a clean temporary dressing on the wound.
4. Wash your hands. Prepare dressings and bandages.
5. Wash *around* the wound (but not the open wound itself) with swabs or clean material moistened with soap and water. Use a fresh swab or material area for each stroke.
6. Cover the wound with a large dry dressing. Over this place a thick soft pad. Bandage firmly.
7. Put the injured part at rest.
8. Take measures against shock (*q.v.*).

Dressings. Gauze from freshly opened pack. Or improvise from clean handkerchief or small towel, held by corners, allowed to fall open and then refolded so that inside surface comes to outside. A leg or arm can be slipped inside a pillowcase.

Padding. Cotton wool. Or improvise from bunched clean handkerchief, sock.

Bandages can be improvised from stockings, necktie, belt.

Object embedded in wound. Do not try to remove it. Cover it with a clean dressing and over this place a "frame" of padding to surround the side of the object and protect above it. You can now apply further padding and bandages without pressing on the object.

Tetanus (lockjaw) is a risk in wounds contaminated with soil or from animals or thorns. Get medical advice.

St. John Ambulance Brigade.

From its origins in 1887, the organisation now boasts many thousand volunteers who deal with over 300,000 casualties each year. These casualties can range from minor upsets such as nose bleeds to victims of heart attacks and broken limbs. The work of the St. John Ambulance is divided into two aspects: the Brigade, which provides volunteers to give first-aid at public meetings *etc.*, and the Association, which is engaged in the task of spreading first-aid education.

THE BLOOD.

Doctors who have made a special study of the blood are known as haematologists. Haematology itself is a complex subject because blood itself is complex and its many functions are not easy to describe and only a brief account is given here. *see also* **Blood groups** (**Z61**) and **Rhesus factor** (**Z61**).

Blood consists of a fluid, called plasma, in which are suspended red and white blood cells and platelets and in which are dissolved many substances from the simple ones like glucose to the complex like hormones, proteins and fats. Total blood volume amounts to about five litres; the blood donor gives about half a litre at a session and feels no ill effects. Loss of a litre or more induces surgical shock (*see* **Physical Injuries and First Aid**). Red cells are red because they carry a protein called haemoglobin which is capable of carrying oxygen. There are about five million red cells for each cubic millimetre of blood (that is an average sized drop), a total of 25 million million circulating in the body at any one time. The life of a red cell is about 120 days; new ones are constantly replacing old ones which are "buried" by the spleen.

The haemoglobin from dead cells is recycled; new cells are generated in the marrow of bones, including the breast bone, from which samples of marrow can be taken by a technique known as sternal puncture. Such samples are studied with a microscope to establish diagnoses of various blood disorders. White cells are of five basic types, the names of which need not concern us here. Each type has a specific function—some act as bacterial scavengers, some are concerned with antibodies (*q.v.*) and some with the general defence system of the body which is concerned with the development and maintenance of immunity to various diseases both bacterial and viral. There are also non-cell particles derived from large cells which the marrow produces. These are platelets, which are concerned with blood clotting. They have the capacity to "stick" to any gaps in blood vessels (such as may be caused by injury or, in the minutest of blood vessels, "wear and tear") and initiate blood clotting. All these types of cells can be studied in the test tube after taking a sample from the patient. This is known as venipuncture, a simple and virtually painless procedure, carried out by doctor or nurse or trained "phlebotomist", by inserting a needle on the end of a syringe into a dilated vein in the crook of the arm. Marrow samples can also be taken, as we have said, from the breast bone—but that is a very different procedure, requiring local anaesthetic and much more skill. For the patient it is not a comfortable procedure either.

Plasma, the fluid part of the blood, is more the province of the biochemist than the haematologist. The immunologist is also interested in plasma and all three disciplines tend to overlap to some degree. Plasma can be studied in the same way as whole blood. A venipuncture is carried out, a chemical added to stop clotting and the cells can then be removed in a centrifuge. If blood is allowed to clot in the test tube, the cells are all caught up in the clot and the plasma remains liquid and can be poured off. It is then known as serum. Plasma contains substances which are either dissolved, that is, in solution, or are held "in suspension". By this is meant that the plasma forms an emulsion because fat particles and some proteins are not soluble and can only form suspensions in this way. The protein and fat particles are in suspension in a like manner. The substances both in solution and in suspension are much too numerous to be dealt with here.

The functions of blood are manifold, but essentially blood is a transport medium, concerned with moving gases (oxygen and carbon dioxide), moving food (protein, carbohydrate, fat, minerals and vitamins), eliminating waste products and protecting and repairing the body.

Red Cell Diseases.

These are of two main groups leading to a shortage of red cells (anaemia), or an excess (polycythaemia). Anaemia is much the more common and there are many different kinds. In all of them the shortage of red cells results in a depletion of the capacity of the blood to carry oxygen. This means that the heart must work harder to send more blood than usual to the tissues, and even so the tissues will often go short. The patient will be persistently tired and listless, and if the anaemia is severe the action of the brain and heart will be seriously impeded, even leading to fainting, cardiac pain, and breathlessness on exertion. All these symptoms, however, can be caused by many other conditions. The only way to be sure they are due to anaemia is by a proper examination of the blood, and even this will not lead to the truth if the picture has been spoilt by the patient taking iron tonics and other remedies of his own accord. Therefore do not dose yourself with tonics, in case you really have anaemia.

Haemorrhagic Anaemia. Anaemia, a shortage of red cells, may be due to a variety of causes, singly or in combination. One very obvious cause is loss of blood or haemorrhage. Following the sudden loss of a half-litre of blood or more, the red-cell-producing bone marrow "factory" will step up its production; but even if it is adequately supplied with all the raw materials such as iron, it may well take many weeks to build up the numbers to normal. A very severe degree of haemorrhagic anaemia is usually treated by blood transfusion. Milder degrees can be treated by taking extra iron, often over a long period of time.

The supply of iron for making new red-cell pigment is nearly always the bottle-neck which limits production. Haemorrhagic anaemia can commonly occur, however, without a sudden severe haemorrhage. From what has been said about the constant replacement of red cells as they wear out, it must be obvious that even if there is only a slight failure to keep pace with the numbers lost, several months of such a failure can eventually deplete the numbers to the level of very severe anaemia.

This situation is common when small amounts of blood are being continuously or repeatedly lost, and here again it is a shortage of dietary iron which is the usual cause of the failure to replace the lost red cells.

Menstrual Loss and Pregnancy.

Normal menstrual loss in women and girls whose diet is on the border-line of iron deficiency is a common cause of progressive tiredness and lack of energy. Where the menstrual flow is heavier than usual, or where it is frankly excessive in older women due to the various common gynaecological disorders, serious anaemia is surprisingly common. During pregnancy a great deal of iron is lost by the mother to the baby, and this, together with the inevitable blood loss at delivery, often makes for a very tired mother indeed, just at the time when there is an enormous amount of work to be done to manufacture milk and attend to all the extra household tasks of baby care. For these reasons it is almost routinely advisable to build up stocks of iron throughout the pregnancy by remembering to take the pills provided. Men as well as women can lose small amounts of blood continuously in later life from gastro-intestinal conditions such as piles, ulcers, and tropical infestations such as hookworm; and here again the anaemia may be just as severe in the long run as that which inevitably follows a sudden, massive haemorrhage.

One extra word of warning. Do not assume because you are pale that you are anaemic. Pallor is a very poor guide, because it is dependent on so many other things, like the blood vessels in your skin, and its thickness and translucency. Nothing but a blood test (which is so easy for your doctor to do) can really tell you if you are anaemic. And if your anaemia is due to a blood-losing condition, then that too must be treated.

Haemolytic Anaemia occurs when for any reason, there are more blood cells than usual being destroyed in the body. This may be because the cells are abnormally fragile, or because normal cells have been attacked by something to which you are allergic, or rarely because you have become sensitive to your own red cells. Sometimes unborn babies have severe haemolytic anaemia, due to an incompatability of blood group (Rh factor) between the mother and the baby, and the same sort of thing happens if incompatible blood is given by mistake in blood transfusion. Up to a point, in mild haemolytic anaemia, the bone marrow can keep pace with the increased loss of cells, but beyond this point anaemia develops.

After incompatible blood transfusions a very dangerous situation results from the effects of the destruction of red cells and the liberation of their products into the blood. One form of jaundice is often produced in haemolytic anaemia, the patient becoming yellow because of the breakdown products of red cells circulating in excess as bile pigments. These latter are normally always present to a small extent due to the normal, comparatively small, rate of destruction of effete red cells.

Aplastic Anaemia is the term given to anaemia due to a virtually total failure of the bone marrow red-cell factory. Sometimes this occurs for no obvious reason. It is sometimes due to a heavy dose of radioactivity or X-rays knocking out the cells of the "factory." It may even be due to cancer cells growing in the bone marrow cavity and not leaving sufficient room for the red marrow cells. It is fortunate that aplastic anaemia is very rare, because it can only be treated by blood transfusions every few weeks for the rest of the patient's life. Very occasionally there have been exceptions to this rule, when the patient's marrow has re-awakened for no apparent reason and suddenly begins to make red cells again. Rapid progress has been made in the treatment of marrow disease with bone marrow grafts.

Pernicious Anaemia. The processes by which red cells are manufactured are complex, and depend, like so many other bodily activities, on the supply of a vitamin containing cobalt, called vitamin B_{12}. This is nearly always present in more than adequate quantities in the diet, but in order for it to be absorbed from the intestine, there must also be a substance called "intrinsic factor" which is normally made by the lining of the stomach. People with pernicious anaemia have suffered a degeneration of the lining of their stomachs, probably because, for some reason, they have become "sensitive" to this part of their own tissue. This kind of civil war within the body is known as an "auto-immune" disease, and is comparable in type with some forms of haemolytic anaemia. In other words they destroy their own stomach lining, fail to produce "intrinsic factor," and as a result fail to absorb vitamin B_{12} into the body. Faced with a failure in the supply of this essential substance, the bone marrow produces too few red cells, and the few that are produced are deformed, much too large, and very fragile. In addition to its role in blood formation, vitamin B_{12} is essential to the normal functioning of the spinal cord, and in long-standing cases of untreated pernicious anaemia, there is often a neurological disability.

Nowadays pernicious anaemia is treated by small occasional injections of the vitamin, whose other name is cyanocobalamin.

Polycythaemia. Too many red cells per cubic millimetre of blood can be found without there being an increase of the total number of red cells in the body. This occurs in dehydration, when there is a loss of plasma without a comparable loss of cells, and is called haemo-concentration. Alternatively, the bone marrow can manufacture more cells than usual as a response to living for long periods at high altitudes. The beneficial result can be that the blood can carry normal amounts of oxygen, even though the supply (in the rarefied air) is reduced.

Finally there is a red cell disease in which the bone marrow factory gets out of control and produces too many cells with no beneficial results. The number in the blood can be double the normal and the blood becomes so thick that the heart has difficulty pumping it round the body.

This disease (*polycythaemia rubra vera*) can be treated by repeatedly bleeding the patient to reduce the numbers of cells. It is now treated very successfully with carefully judged amounts of radioactive phosphorus or certain other "antimitotic" chemicals which reduce the rate of multiplication of bone marrow cells.

White Cell Diseases.

Diseases of the white cells are very much less common but are inevitably serious.

Agranulocytosis. In this condition the number of those white cells which are responsible for phagocytosis of bacteria falls precipitously. The result is that one of the main bodily defences against infection fails, and the patient may die from an overwhelming invasion of germs and the accompanying high fever. The usual cause is abnormal sensitivity to a variety of drugs, often those which are in widespread use and only give trouble in the occasional case. One example among hundreds is the antibiotic chloramphenicol which specifically kills typhoid bacteria and is used for that purpose. It is believed that about one patient in 60,000 becomes sensitive to it and agranulocytosis often fatally follows, though appropriate treat- ment of infections has greatly reduced the likelihood of death. The fact that almost any drug *can* do this to some people and yet be quite safe for the majority, is one good reason not to dose yourself with over-the-counter medicines.

Leukaemia comprises a range of diseases which involve the abnormal production of white blood cells. Immature or blast cells are produced at an increased rate and tend to infiltrate various areas of the body, for example, bone marrow, lymph nodes and spleen. They are also found in the peripheral blood and cerebrospinal fluid. In spite of their large numbers these cells, because of their abnormality, are unable to deal effectively with infection and anaemia, sepsis and fever can result.

The cause of this cancer is open to speculation but we know there is an increased incidence in those with Down's Syndrome and other chromosomal abnormalities. Viral infections may also be implicated and there is almost certainly an association with ionising radiation.

This latter fact was proved by the increased incidence of leukaemia in those who survived the atomic bombs in Japan at the end of the Second World War. Pregnant women should not be subject to X-Rays as this may cause an increased incidence of leukaemia in their children.

Further research has suggested that workers exposed to small amounts of radioactive material may suffer abnormal spermatic development so that the tendency to leukaemia may be passed on to their unborn children who may be prone to the disease later in life.

The outcome of the illness largely depends on the specific type. Chronic lymphatic leukaemia for example, which tends to affect older people, may have no clinical signs or symptoms. In fact, it can run a very indolent course, require no treatment and be compatible with a normal lifespan. On the other hand, acute myeloid leukaemia which tends to affect younger adults is a very serious disease with an acute onset and which if not treated can prove to be rapidly fatal.

A new treatment which triggers the immune system to attack cancer cells has increased survival rates.

Chronic Myelogenous Leukaemia (CML) results from a particular "translocation" of cellular DNA. The DNA is swapped to an unusual place and instead of working normally, produces an abnormal protein. A new treatment, Glivec, that blocks the abnormal protein, has demonstrated some dramatic improvements in patients.

Childhood Leukaemia is the most common form of childhood cancer, but nevertheless it is quite rare with an incidence of approximately 25 per 1,000,000 children. Over 85% of all cases involve the type known as acute lymphoblastic leukaemia. With modern treatment, a remission (that is to say, a disease free period) can be induced in over 90% of children and cure rates are very high. Presenting features of acute leukaemia are tiredness, lethargy, abnormal susceptibility to infection, excessive bruising and occasionally bone or joint pain. A blood count usually helps in the diagnosis but this needs to be confirmed by examination of the bone marrow. Treatment involves repeated courses of cytotoxic drugs, sometimes combined with radiotherapy. For those with more resistant forms of the illness, bone marrow transplantation can often provide a cure. Treatment is best performed in specialist centres where the expertise is available to deal with the complicated drug regimes. With modern treatment the outlook for all forms of leukaemia has much improved. For children, in particular, the outlook has been dramatically transformed and in a great many cases a cure can be successfully achieved. Further information can be obtained from the Leukaemia and Lymphoma Society.

Hodgkin's Disease is a disease in some ways akin to *leukaemia.* Abnormal cells are found in the reticulo-edothelial system and proliferate in a disorganised manner, causing enlargement of lymph nodes (glands), spleen and sometimes the liver. Hodgkin's disease, named after a 19th cent. Guy's physician, has been the subject of much research and therapeutic trial. The improvement in outlook for patients with Hodgkin's disease was one of the major success stories of the 1990s. In cases where the disease is caught early, it can be eradicated in over 95 per cent of sufferers (although progress has been less marked with non-Hodgkin's lymphoma).

Hæmorrhagic or Bleeding Diseases.

Whenever blood vessels are damaged by injury, there is a remarkable series of mechanisms which automatically come into operation to stem the flow of blood. There is a constriction of all the smaller vessels in the locality. Platelets stick together and release substances which help the vessels to stay constricted as well as others necessary to blood clotting, and yet others which help to bind the clot tightly together. Later, materials appear to prevent too much clotting, and eventually the clot is removed altogether as healing proceeds.

There are some very complicated diseases of this blood-conserving mechanism which can lead to abnormal bleeding, sometimes beneath the skin to produce bruising or even smaller leaks; sometimes leading to a greater loss of blood, particularly following a wound. In some kinds of *purpura* (bleeding tendency) the blood vessels are the cause of the trouble, having become fragile and leaky for a number of reasons. This happens in old age (*senile purpura*), in scurvy, or vitamin C deficiency, as an occasional accompaniment to infective diseases, or as an immunological effect on the lining of blood vessels when the patient becomes sensitised to certain substances (*SchönleinHenoch* or *anaphylactoid purpura*). The latter often follows a streptococcal sore throat, just as rheumatic fever and acute nephritis do; and as well as the purpura there may be joint pains and nephritis. Just as almost any drug or chemical will cause agranulocytosis in some people, so it can also cause anaphylactoid purpura.

Purpura may also be due to a lack of platelets, known as thrombocytopenia (a shortage of thrombocytes or platelets). This can happen if the bone marrow factory is depressed, since this is where platelets too are made. It is therefore a common accompaniment of leukaemia or aplastic anaemia. Or there can be increased destruction of platelets in some diseases of the spleen. Platelets normally last eight to ten days, but their lifespan can be shortened in heart failure, and following massive transfusions, or often for no apparent reason ("idiopathic" thrombocytopenia), when the removal of the spleen can sometimes help.

Clotting Mechanism Defects. Defects of the *clotting mechanism* will lead to a bleeding tendency, and since the mechanism itself is very complex, so is the variety of things which can upset it. The liver provides the blood with many of the substances required for clotting, so it is not surprising that a clotting defect commonly accompanies liver disease. One necessary substance for blood clotting is called "antihaemophilic factor" and is missing from people who have inherited the disease *haemophilia*. These people may die of haemorrhage from quite small cuts or minor surgical procedures.

THE HEART AND BLOOD VESSELS.

The heart consists of about 350g of muscle which makes up the walls of its four chambers. Anatomically the human heart closely resembles the sheeps' hearts to be found in a butcher's shop. Indeed it would be an instructive exercise to dissect one of these in the order described below, since there is no other way of properly appreciating what the chambers, valves, *etc.*, are really like.

There are two quite separate pumps in the heart—one on the owner's right (or on your *left* if you are looking at the front of someone else), and one on his left. The right heart collects spent, deoxygenated, "venous" blood which returns there from the whole of the body, and gives it the comparatively small push required to drive it through the adjacent lungs. The left heart collects the revitalised, oxygenated "arterial" blood as it leaves the lungs, and gives it the enormous push required to build up the arterial blood pressure, so that it can be forced through all the tissues of the body. As may be expected, the right heart chambers have much thinner walls than the left, since their muscle has less work to do. This will help you get your bearings with the sheep's heart. The tip, or apex, is the lowest part. The thick-feeling side is the left, the thin the right; and the great vessels are at the top.

The Right Atrium.

The upper chamber on the right, or right atrium, has two large openings into it through which all the spent blood arrives from the upper and lower great veins (the superior and inferior venae cavae). Cut open the thin wall of the right atrium with scissors between these two holes to lay open the interior of the chamber, noting the "auricle" or "dog's ear" that forms a small cul-de-sac. The whole chamber is sometimes, inaccurately, called the auricle. You should be able to push a finger downwards into the lower chamber—the right ventricle—through a communicating hole guarded by the three thin cusps of the *tricuspid valve*. These will not obstruct your finger, since they are designed to permit blood flow in the same direction.

The Pulmonary Valve.

When the atrium is full of blood, it squeezes its contents through the tricuspid valve into the right ventricle; and when, a split second later, the ventricle is full and contracts, the three cusps come together to prevent the blood from flowing backwards into the atrium again. Instead the spent blood is driven onwards through the *pulmonary valve* (in the upper part of the right ventricle), through the pulmonary artery, to be delivered to the lungs. The pulmonary valve has three very well-defined cusps which prevent blood from coming back into the ventricle as it relaxes to receive more blood from the atrium before the next contraction or beat.

It is possible to pass a blade of the scissors from the opened-out right atrium, through the tricuspid valve towards the tip of the heart, and cut along the right border of the heart through the thickness of the ventricular muscle. Then cut upwards again, passing the scissors blade through the pulmonary valve and open up the *pulmonary artery*. If you have done this successfully you will have followed the path taken by the spent blood through the right heart to the lungs. Notice the thick round bands of muscle lining the ventricle, and notice too that you have not entered the left heart, which has no connection with the right except in some congenital malformations (*see later*).

The same dissection can now be made of the left heart. Open up the *left atrium*, noting its "dog's ear" or "auricle," pass the scissors down into the *left ventricle* through the two rather flimsy cusps of the *mitral valve*. Notice how much thicker is the muscle of the left ventricle, and cut upwards through the three well-formed cusps of the *aortic valve* into the main artery of the body—the *aorta*.

The Coronary Arteries.

The aorta as it leaves the left heart is distinguishable from the pulmonary artery as it leaves the right, partly by the extreme toughness of the aortic wall (it has to withstand so much more blood-pressure); and partly by the entrances or orifices of the two small branches given off by the aorta, just beyond the valve cusps, which go to supply the heart muscle itself with blood. These are the *coronary arteries* which are so necessary for the heart's own survival.

Cardiac Output.

The amount of blood pumped in unit time, or the *cardiac output*, can be varied a great deal, according to the needs of the moment. This is accomplished by altering both the heart rate and the stroke volume, the amount expelled per beat. Every minute, the healthy adult man at rest shifts about 5 litres of blood through the heart—an amount equivalent to all the blood he possesses. When exercise is taken, or in response to anxiety or fear, this is stepped up many times, so that the muscles can receive a greatly augmented supply of the materials required for action. The controlling mechanisms which allow these changes to be made automatically are partly organised in the brain by the so-called *cardiac centre*; and partly by local mechanical and chemical stimuli to the heart muscle itself. The cardiac centre is continuously receiving information through nerves about the physical and chemical state of the circulation, and also from the mind; which is partly how certain emotions make the heart beat faster. All the information is integrated, and a cardiac output continuously arranged which is appropriate for current demands.

Cardiac Neurosis. In ordinary circumstances at rest, most healthy people are not conscious of their heart-beat. However, there are many perfectly healthy people whose hearts slip in an extra beat occasionally. Sometimes their owners are aware of this and become unnecessarily alarmed. Their fear causes palpitations (a pounding of the heart) and the tension mounts. An undue anxiety about the tricks played by a healthy heart sometimes leads people to interpret minor pains in the chest, or even indigestion, as grave symptoms of heart disease, and the consequent anxiety leads to still worse symptoms. If you are one of these worried people, take your worries to your doctor, and let him decide for you whether there is anything wrong. A hundred to one there isn't.

Many people secretly worry about heart disease and high blood-pressure for years, when very often they are worrying unnecessarily. Even if there is cause for worry, so much can be done for these conditions (as it can for cancer) provided medical advice is taken early in the course of the disease. Remember, too, that the slight feeling of giddiness when you get up suddenly from having been lying down, is often experienced by most normal people; but if you get frightened by it you will begin to breathe more quickly and deeply; and this in itself will make you feel even more faint—and so on.

Heart Failure. When the cardiac output of blood is too little for the requirements of the body, a state of *circulatory failure* has arisen, and when this is due primarily to the heart itself being at fault, it is more properly called *heart failure.* As will be seen, heart failure is not a disease, but the common result of a large number of different diseases. The signs and symptoms produced are caused by two sorts of process: (*a*) tissues of the body have too little blood flow through them and are therefore undersupplied; (*b*) blood accumulates and stagnates in tissues, causing congestion, since the failing heart cannot move forward the amount of blood presented to it in the great veins.

Often the left or right side of the heart fails disproportionately. In *left heart failure* the lungs are congested because they are the territory from which the left heart is failing to move blood. The patient has great difficulty with his breathing, and in advanced cases may not be able to breathe when he lies down, because the lungs become so congested and waterlogged. In *right heart failure* the main veins are congested and the other parts of the body become swollen with excess tissue fluid, mainly in the lower parts such as the legs and ankles.

This swelling with fluid is called *oedema*, and in heart failure is only partly due to the mechanics of the failing heart. It is mainly due to the retention of sodium in the body, a situation in which excess water is also retained.

Whatever the actual type of heart failure it is always likely to be a changing condition, since the amount of failure will depend as much on the demands being made as on the state of the heart. For instance, in mild cases at rest when the required cardiac output is small, there may be no signs or symptoms. These may only appear on exertion. Heart failure will be referred to again under the various conditions which cause it.

Treatment of Heart Failure is quite logical. It is aimed at correcting the imbalance between supply and demand of blood, and at the removal of the accumulated excess fluid. We can therefore (*a*) reduce the body's demand for blood; (*b*) increase the supply or cardiac output; and (*c*) promote the excretion of sodium and fluid. Demand for blood is reduced by rest, both physical and mental, and by reduction of weight, since obesity (being overweight) is an additional demand on the cardiovascular system. The cardiac output can be increased by administering a "tonic" to the heart muscle in the form of *digitalis*, which is a powerful heart stimulant derived from foxglove leaf. Fluid (and hence salt) accumulation can be helped by restricting the intake of salt and by giving drugs which promote its excretion by the kidneys (diuretics). Very occasionally, very large accumulations of fluid in the legs, abdomen, or thorax, are tapped and drained physically, with needles. These remarks are of course very general and must not encourage anyone to treat himself for such a potentially serious condition as heart failure. Even such a simple measure as doing without salt can be practised quite unnecessarily by many people for years, simply as a result of reading a paragraph like the above. If you need to reduce salt intake you should be in your doctor's care, and so please let him or her decide.

Congenital Heart Disease. It has been estimated that of all the babies born who survive at least one month, there will be about one in every two hundred with some form of congenital heart disease; that is to say that the heart will have failed to develop properly in embryonic life. In some cases this is associated with a virus disease of the mother (commonly rubella, or German measles) or with certain drugs taken by the mother (*e.g.* thalidomide) at a time, very early in pregnancy, when organs are assuming their adult shape. Parents should see to it that their daughters get German measles vaccine before they grow up; and drugs of all kinds should be avoided where possible during early pregnancy. In most cases of congenital heart disease, however, there is no known cause, and it seems that the manner of formation of the embryonic heart is so delicate that it can be thrown out of gear very easily, perhaps even by chance. Scores of different types of defect occur, singly and in combination.

Any of the valves may be anatomically defective—either failing to close properly (*incompetence*) or being too tight (*stenosis*); the great vessels (pulmonary artery and aorta) may be switched round, or *transposed*, so that they emerge from the wrong ventricle; there may be defects in the wall (*septum*) which separates the atria or the ventricles on each side (*septal defect*, or "hole in the heart"); or there may be a persistence of the vessel which in the foetus normally by-passes the lungs by joining the pulmonary artery to the aorta (*patent ductus arteriosus*). This vessel normally closes at the time of birth when the first breaths are taken, and subsequently disappears, so that the whole output of the heart is then sent round the lungs. Detecting congenital heart disease early is one of the purposes of routine post-natal check-up examinations of the baby. Exact diagnosis requires very complicated techniques, and sometimes the structural defect can be corrected by surgery, with almost miraculous results.

Rheumatic Heart Disease. Acute rheumatic fever is not to be confused with other forms of rheumatism. Many tissues of the body (particularly the heart) are attacked, as well as the joints, and the trouble is due to a sensitivity which has developed to certain bacteria (*haemolytic streptococci*) which have probably caused a sore throat about three weeks before the onset of the disease. Why acute rheumatism only rarely follows streptococcal sore throat is poorly understood, but this is no consolation to the one per cent or so of the population whose hearts bear its scars. During the acute phase of the illness which usually occurs before the age of fifteen, inflammatory damage occurs to the valves, the heart muscle, and the sac in which the heart lives, the *pericardium*. So there is a *valvulitis* or *endocarditis*, a *myocarditis* and a *pericarditis*. There may be acute heart failure at this stage if the heart is severely affected. The better-known results of rheumatic heart disease, however, are caused in the ensuing years by scarring of the healed valves. The valves are thickened and deformed. They may have lost their elasticity and stretch, so that they do not close properly (*incompetence*); or they may contract and tighten (*stenosis*). In both cases the heart chamber situated next to the affected valve has to work progressively harder, either because it gets no rest in between beats (in *incompetence*); or it has to force the blood through too narrow a hole (in *stenosis*). The end result is some variety of heart failure (*q.v.*).

Mitral Stenosis. The most commonly affected valve is the mitral, usually causing *mitral stenosis*, in which the opening between the left atrium and the left ventricle will sometimes only admit one fingertip instead of three fingers as it should. In time the left atrium becomes much enlarged as it overworks to force blood through this narrow orifice. Later still a back pressure develops in the lungs causing congestion and breathlessness; and even later the right ventricle is strained as it tries to force blood into the already congested lung. This is a classic example of the march of trouble backwards from the site of the damaged valve involving first the chamber "behind" it (the left atrium), then the territory "behind" that (the lungs), then the pulmonary arteries taking blood to the lungs, and finally the right ventricle trying to send blood to the pulmonary artery. This steady march of events is usually very slow, and can commonly take twenty years or longer from the initial attack of acute rheumatism to the severer symptoms of advanced mitral stenosis. Treatment is both medical and surgical. The heart failure is treated medically as already described. These days surgical reopening of the valve is almost commonplace, either by inserting a finger through the left auricle and breaking down the constriction, or by opening up the heart and re-shaping the valve under direct vision. The latter involves the additional problem of bypassing the heart by the use of some sort of external pump and poses additional problems, even though from other points of view it is obviously more convenient.

As always with major surgical procedures much of the problem is in selecting the patients who will benefit from the operation and in whom it is feasible. Quite often there are other valves involved, mainly the aortic or tricuspid or both, and the hydrostatic or "plumbing" problems can be extremely complex. With luck, however, combined with good judgement and good surgery, the lives of incapacitated patients can be transformed by mitral, and other valvular, surgery.

Aortic Valve. The *aortic valve* is stenosed or narrowed by other degenerative processes besides rheumatism. *Tricuspid stenosis* is nearly always rheumatic in origin.

Coronary Heart Disease. This is the term used whenever the blood supply to the heart muscle (through the coronary arteries) is reduced to such an extent that the heart muscle suffers from a lack of supplies. It has a number of causes, but the only really common one is partial obstruction of the coronary arteries by a condition known as *atheroma* or *atherosclerosis*, and sometimes inaccurately called *arteriosclerosis*. This arterial disease is described later (**Z29**). It takes the form of swellings or lumps on the lining of the artery which, if they become large enough to interfere seriously with the flow of blood, produce a blood starvation or *ischaemia* of the tissue being supplied. Obviously, the smaller the artery, the more easily will a lump of given size impede the flow. Equally obviously the greater the demand for blood, as in exercise, the more blood "starvation" there will be. There are two degrees of coronary artery disease: one in which the blood flow is reduced to the point where the increased demands of hard work cannot be met, and this results in *angina pectoris* due to *coronary insufficiency*; the other is when the coronary artery becomes completely blocked, preventing the flow of blood, usually by a *thrombus* or clot of blood, and this is *coronary thrombosis*, or heart attack.

Angina Pectoris. Whenever activity is increased in any muscle, the demands for oxygen and nutriments from the blood-stream increase, and as these are used up there is an increased production of waste products known as metabolites. To meet the demands for a greater supply and a more efficient waste-disposal, the blood flow through the exercising muscle must always be increased. If sufficient increase does not occur, not only will there be a shortage of supplies, but there will also be a pile-up of metabolites in the muscle which cannot be carried away. It is mainly because of these latter that pain is caused in ischaemic, or blood-starved muscle, and pain is one of the chief symptoms when heart muscle becomes ischaemic. One important mechanism for increasing blood flow normally to exercising muscle is by automatically dilating the vessels concerned. Diseased vessels, such as coronary arteries when they are affected by atheroma, are not so easily dilated, although certain drugs which are powerful dilators of arterioles can accomplish a great deal, albeit temporarily. The measures taken to relieve the pain and blood-starvation of angina are two-fold. The patient can reduce the demands of the heart by a rest, and a drug (usually nitroglycerin) can be taken to dilate the coronary vessels of supply.

Another obvious long-term way to reduce demands is for the overweight patient to eat less, and reduce the load of extra body weight on his circulation. It is very frustrating, to say the least, that such an incapacitating and often lethal condition should be caused by the narrowing or blockage of only 5 or 8 cm of narrow piping about 3·5 mm wide. Coronary bypass operations in which the blocked segment is replaced with a piece of blood vessel taken from another part of the body, are now fairly routine.

Angioplasty is where a small balloon, on a wire, is guided into the narrowed arteries of the heart. The balloon is then inflated, opening up the obstructed vessel and allowing adequate blood to reach the heart beyond the narrowing.

Heart Attack (Myocardial Infarction) or Coronary Thrombosis. It should readily be understood from the above description that heart attacks will vary in their severity according to the amount of heart muscle deprived of blood; and this in turn will depend on where in the coronary artery the obstruction occurs. Most usually it is the left ventricular muscle which is cut off from supplies and dies, either in part or in all of its thickness. Since it is the left ventricle which does most of the work of pumping blood, serious heart failure is to be expected.

If too much muscle is killed, the heart will simply stop, and the patient will suddenly die. It is much more usual, however, for enough muscle to be left for survival, albeit with a greatly reduced cardiac efficiency. A heart attack is usually accompanied by severe pain, similar to the pain of angina but more severe, and unrelieved by rest or by the patient's usual drugs. Very occasionally the event occurs apparently without pain, or with so little that it is ignored. These so-called "silent" coronary attacks can make diagnosis extremely difficult. Since the doctor depends very considerably with heart attacks on an exact, spontaneous description of symptoms for his diagnosis, no description will be given here. There are many over-anxious people who will read these words and could be misled into an unspontaneous description of their own symptoms, and this could make the task of treating them such a problem that they could even be mis-diagnosed as a result. If you have the smallest worry that your chest pain is due to your heart, take your anxiety to your doctor without delay. He will almost certainly be able to reassure you; and if it happens to be your heart after all, you will have taken the first sensible step towards proper treatment. Dangerous as heart attacks are, they are by no means the death warrant that many lay people think, any more than cancer is. The treatment for a true heart attack is urgent and prolonged. Patients must be at complete rest and their pain relieved quickly. The area of heart muscle they have lost must be allowed to heal. Nowadays patients are encouraged to mobilise early, and progressively increase activities over a few days to weeks.

You can help to avoid a heart attack by not smoking, avoiding obesity and living a physically active life. Avoid sudden exercise, however.

Blood Pressure (Hypertension). The blood is under great pressure in the arterial system, since it is this which forces it into all the tissues of the body. It is therefore no more meaningful to say you have "blood pressure" than to say you have a temperature. You would be very badly off without. Blood pressure which is too high (hypertension) can give rise to problems, though not always. It is another of those conditions like angina and cancer, which engender much anxiety among people even when they do not suffer from them.

It is not being suggested here that high blood pressure is a trivial condition, but that it is for doctors to worry about rather than patients! If you ever find out your own blood pressure, never try to work out for yourself what the figures mean. It is much too complicated. Finally, it should be mentioned that high blood pressure may occasionally be associated with, or "secondary to," certain kidney diseases (*nephritis*) including a strange condition known as *toxaemia of pregnancy*, which lasts only as long as the pregnancy, provided great care is taken. Most high blood pressure is "primary", and without any known association or cause. A radical new method of tackling hypertension could involve severing nerves that carry signals from the kidneys to the brain.

In 2010, there were an estimated 1,000 *million* people globally with high blood pressure (a reading of over 140/90 mm of mercury). This number is expected to more than double by 2025.

Low Blood Pressure. Some people seem normally to have surprisingly low blood pressure all the time. There is nothing whatever wrong with this; indeed it may even be beneficial. At least they are unlikely ever to suffer the effects of high blood pressure. The sudden low blood pressure of circulatory failure or shock (**Z27**) is another matter and must be urgently treated.

Irregularities of the Heart Beat. How quickly or how slowly the heart beats is largely under the control of the cardiac centre in the brain and the level of certain hormones in the blood. The *regularity* of the beat, however, is controlled by the so-called pace-maker in the wall of the right atrium, and by the way impulses from the pace-maker travel through specialised conducting heart cells (the bundle of His and its branches) to the ventricles. When any part of this elaborate mechanism is upset, either by altering the biochemical or electrical conditions of these specialised tissues, or by killing some of them off by deprivation of blood supply in the course of a heart attack, disordered rhythm can result. Increase (*tachycardia*) or decrease (*bradycardia*) in rate is nearly always a normal response to exercise, or anxiety. Very occasional irregularity, such as the mis-timing of an occasional beat is also quite normal in some people, although many are alarmed by it. Persistent irregularity, however, is abnormal. Its true nature can usually be elucidated by making an electrical record of the heart beat—an electro cardiogram.

The commonest causes are varieties of coronary artery diseases or rheumatic heart disease.

Pericarditis. The heart beats inside a bag or sac. At every beat its outer surface slides against the lining of the sac, lubricated by a small amount of fluid. This is the pericardial sac, the *pericardium* being strictly the lubricated membrane which lines the sac and which also covers the outer surface of the heart. Sometimes inflammation occurs—*pericarditis*—and the sliding surfaces become roughened and even separated by a fluid effusion. Very occasionally, so much fluid accumulates that the heart's action is seriously impeded. Pericarditis may be due to infection or to rheumatic fever, and it usually overlies the area of damaged muscle after a heart attack. This illustrates something which people rarely appreciate—that inflammation is not by any means always due to infection by bacteria. The last two varieties of pericarditis are quite free from germs (sterile).

Myocarditis. A term loosely applied to disorders affecting the heart muscle. There are lots of very rare causes. The really common ones are due to acute or chronic rheumatic causes or to coronary artery disease.

Endocarditis or inflammation of the lining of the heart is a term loosely applied to any disorder of the valves or heart lining. All varieties of rheumatic valvular disease (**Z27**) are included. Bacterial endocarditis in its several forms usually involves valves already damaged by rheumatic disease. It is a complication which is still much to be feared, though somewhat less so now that antibiotic drugs are available.

Atheroma or Atherosclerosis. This is the condition referred to above in which lumps arise on the lining of arterial blood-vessels. Although it is therefore a disease of the arteries, its importance lies in the way blood flow is held up, either by the lumps themselves, or by thrombosis ultimately blocking the narrowed portion of the pipework. The effects on the body are therefore those of depriving the tissues of blood.

It is an astonishing fact that in England and America, more people die of the consequences of atheroma than of any other single disease, including all forms of cancer put together.

Intermittent Claudication. If narrowing of the artery is going to do major harm it is easy to see that it will be of more consequence in those parts of the body where small-bore vessels are supplying tissues whose functions are necessary for life. Exactly such a situation exists in the heart and in the brain. An additional factor is that the arrangement of the blood supply in these tissues is such that any particular area has only one vessel leading to it. This is unusual among the tissues generally, where several alternative, or "collateral" vessels usually supply an area, and where others can take over if one becomes obstructed. We have, therefore, a situation in which perhaps the most important tissues—the heart and the brain—run the greatest risk of deprivation, and this leads to angina and coronary thrombosis on the one hand, and cerebral thrombosis and haemorrhage ("stroke illness") on the other, accounting jointly for about one death in every five. In addition, the effects of atheromatous narrowing are often felt in the legs, where the blood supply to the muscles is inadequate for exercise, leading to intermittent pain comparable with that in the heart in similar circumstances. This is called *intermittent claudication*, or intermittent closing of the leg arteries. In its most severe forms, it leads to the need for amputation, although in most cases early treatment can avoid this. There is intensive research into the causes of atheroma.

Raised Cholesterol. A lot of attention has been given to the amounts of certain fats in the circulating blood, particularly cholesterol. This fat is found in larger amounts in the blood of sufferers from atheroma, and is also found in the arterial lumps themselves. Efforts have therefore been made to reduce blood cholesterol by modifications of the diet, but it has been extremely difficult to prove that this has done any good. Many other factors are known to contribute to atheroma, and hence to heart attacks and strokes, some of which can be reduced and others not. Such factors are age, obesity, high blood pressure, and smoking cigarettes.

People who lead an active life seem to have less trouble than others who are less active. Sudden severe exercise, however, is bad if you are not used to it. It is better, and life saving, to take regular, moderate exercise. Women have less atheroma than men, until the menopause when they begin to catch up, so that hormones have something to do with it.

Aortic Disease. The aorta, the main artery of the body, running from the left ventricle down through the chest and abdomen, also suffers from atheroma, but is too wide (about 2·5 cm across) to become obstructed. However, weaknesses occur in the thickness of its wall, sometimes due to syphilis but nowadays much more usually due to atheroma, which results in a ballooning out of a part of the vessel, rather like you sometimes see in an old bicycle inner tube. In days gone by these *aneurysms*, as the dilations are called, reached an enormous size, and would wear away the breastbone and ribs, to appear as large pulsating masses on the chest. Now that advanced syphilis is less common, atheromatous aneurysm, with a predilection for the abdominal aorta, is the one most commonly seen; and these days it is treated by replacement of the diseased portion of vessel. *Dissecting aneurysms* of the aorta are another variety in which the blood, under high pressure, somehow finds its way in between the layers of the aortic wall and then suddenly rips up and down the whole length of the vessel, separating (or dissecting) one layer from another in its path. Sometimes it tracks back towards the heart and suddenly fills the pericardium with blood to stop the heart's action altogether.

Embolism. This term refers to any object travelling in the circulation and becoming impacted when it reaches a vessel too small for it to pass through. It may be a thrombus (**Z30**), a collection of cancer cells, a group of bacteria, a chunk of infected pus from an abscess, a collection of fat droplets or even a bubble of air. If it originates in a vein it travels to the right heart and to the lungs. If it comes from the left heart or an artery, it will impact in any part of the arterial tree. Reasonably enough an arterial embolus will commonly end up in those parts of the body with the richest blood supply, like the brain, the kidneys, the liver or the bone marrow. A thrombotic embolus will cause death of the tissue in the area previously supplied by the blocked vessel, a condition known as *infarction*. Perhaps the commonest source of thrombotic embolism is the lining of the heart chambers where a thrombus has occurred at the site of muscle damaged by a heart attack.

Pulmonary Embolism. Cases of massive *pulmonary (lung) embolism* are usually the result of the thrombosis of the leg veins in people kept immobile following surgery or childbirth. That is why postoperative patients are got out of bed for a while as soon as the first day after the operation. The cells of a cancer embolus usually die; but if they survive, a new cancer deposit begins to grow where the embolus impacts, and this is one of the ways cancer may spread. An infected embolus may infect the vessel wall when it impacts, producing a weakness which may give way. Air embolism, if enough insoluble gas enters the circulation, can kill by making so much froth in the heart chambers as to impede the normal pumping action. If bubbles pass the lungs and enter the brain, all sorts of neurological disorders like scores of tiny strokes arise. The same sort of thing happens all over the body in the "*bends*" or "*caisson*" *disease*, in which nitrogen dissolved in the blood at high pressure, usually in deep-sea diving, bubbles out of solution if decompression is too rapid. Fat embolism sometimes occurs after fractures, due to marrow fat entering damaged veins and being carried away to the lungs.

Thrombosis. This is not quite the same as clotting. It is the mass which arises when platelets adhere to the lining of blood-vessels or heart chambers. Blood clot accumulates among layers of deposited platelets and the thrombus therefore has structure, unlike pure blood clot. Thrombosis usually occurs when the lining of the vessel or chamber is damaged by atheroma or inflammation, or when the circulation becomes very stagnant. One danger is that it will become dislodged and travel as an embolus during the first week or ten days of its existence. After this time it is usually firmly incorporated into the vessel walls by cells which migrate into it from the surrounding tissue. The other danger is, of course, that the tissue previously supplied by the blocked vessel will die before a collateral circulation can be established. As previously explained, this is called infarction. All the technical terms in this section are used elsewhere and can be looked up.

Varicose Veins. When veins become swollen they also often become tortuous (wriggly), and particularly on the surface of the leg look very unsightly. They are, however, a sign of a sluggish circulation, and are often due to disease in small valves within the veins which normally prevent the blood from pooling backwards, down towards the feet. They are often a normal maternal accompaniment of pregnancy and disappear after the child is born. If allowed to persist, the sluggish circulation allows the formation of unpleasant ulcers, mainly in elderly people. Treatment is according to severity. In the early stages they are helped by supportive stockings. Later, often as an out-patient, the sufferer may have to have them removed. Modern treatment includes microwave or laser therapy.

Raynaud's Disease. This is a strange condition in which the finger tips and in severe cases all the fingers or the whole hand respond in an exaggerated way to cold. The vessels supplying the hand are constricted and the fingers go white as the blood drains from them. Then the capillaries dilate and become distended and filled with blood. But owing to stagnation it is venous and blue, and the fingers are therefore blue. Now we have all experienced this in very cold weather, but sufferers from Raynaud's disease, nearly always women, respond even to very slight cold, like putting their hands into cold water. Even emotional stress will start the process off. In very severe cases the fingers will be so deprived of blood for so long, that sores will develop and fingers can even be lost, but this is very rare, and can be avoided by an operation to cut the nerves which supply the circular muscle of the vessels concerned. In most cases it is sufficient to avoid getting the hands cold. Medicine such as nifedipine can help.

Frostbite. Strictly speaking, this is literally a freezing of the tissues and usually only occurs at temperatures below −13° C. The patient may feel a pricking feeling at first, and feel an area of firmer, pale skin on the cheeks, nose, ears, fingers, or toes. If these parts are numb with cold, the onset of frostbite may not be felt, and will often only be noticed by others. It is important not to rub the affected part nor to apply direct heat in any form. Rapid warming can be harmful; but re-warming by close application of body temperature is good treatment, *e.g.*, fingers can be firmly held in the armpit or a warm hand closely applied to an ear or a nose.

THE RESPIRATORY SYSTEM.

When air is drawn in during the process of breathing, it is brought into very close contact with the blood passing through the lungs. In this way the air we breathe in, which contains 21 per cent oxygen, is confronted with "spent" blood returning from the tissues which contains much less, and oxygen therefore diffuses into the blood from the air. At the same time, the waste gas, carbon dioxide, passes by diffusion in the reverse direction from the blood into the air, because there is much more carbon dioxide in the returning "spent" blood than the tiny amount in the air we breathe. The blood is therefore continually circulating through the lungs and exchanging carbon dioxide for oxygen from the air we breathe in. When we breathe out, we disperse the carbon dioxide into the atmosphere.

The Trachea (Windpipe). When the air enters the nose or mouth, it passes into the windpipe or *trachea*, through the vocal cords in the larynx. The trachea is held open all the time by rings of cartilage and is lined by a mucus-secreting membrane covered by millions of tiny "hairs" or cilia. These continuously waft a sheet of sticky mucus upwards, which traps any dust or other small particles we may have inhaled, until a collection of this material in the pharynx stimulates us to cough and expel the phlegm, usually to be swallowed.

At its lower end, the trachea or windpipe divides into two, the right and left main *bronchus*. Each main bronchial tube enters a lung, one on each side, and proceeds to divide repeatedly within the lung until the air is being carried by more and more smaller and ever smaller tubes called *bronchioles*. There are many millions of these on each side, and each one ends in a collection of very small balloon-like structures—the air sacs or *alveoli*. If you were to cut across a lung and examine the cut surface in a good light, you would see that it is a spongy tissue, with many millions of tiny holes, each one just visible to the naked eye. These are the air sacs. In their walls run the blood capillaries, each one of which is a branch of the vessels carrying "spent" blood from the right side of the heart. At this stage, the blood is only separated from the air in the sacs by the walls of the capillaries and of the air sacs themselves. Both structures are extremely thin, making for easy diffusion of the gases between blood and air.

The Breathing Mechanism. This is achieved by two muscular mechanisms. One is by the muscles which move the ribs, and the other by the diaphragm, a sheet of muscle which runs across the body, separating the chest cavity from the abdominal cavity. These muscles are all actuated by nerves, just as all other muscles are. Those running to the muscles of breathing are organised by a mechanism in the brain known as the *respiratory centre*. It is this centre—one of the so-called vital centres of the brain—which receives information from many different sources, and translates it into instructions for the breathing mechanism.

Thus, when you run for a bus, you will automatically breathe more deeply and more quickly because the respiratory centre has been informed about all the extra carbon dioxide in your blood which has been produced by the exercising leg muscles. Even the conscious instructions involved when you blow a trumpet or inflate a balloon, all pass first to the respiratory centre. It is the death of the cells of this and other vital centres of the brain that is the ultimate cause of death.

Bronchitis may be acute or chronic. It is an inflammation of the lining mucous membrane of the larger air passages or bronchi, and results in much more secretion than the amount normally produced, mixed with some pus. The acute form is often caused by viruses, with "secondary" infection from bacteria. It may sometimes be caused by irritant gases, like the sulphur dioxide in smog. The chronic, or long-standing form of bronchitis is often associated with *emphysema*, in which the small air sacs of the lung architecture are destroyed or distorted, leaving larger spaces than normal, often surrounded by fibrous scar tissue. Such an arrangement makes the normal gaseous exchange difficult between air and blood.

Smoking causes chronic bronchitis and emphysema, as well as lung cancer (see **Z33**). These illnesses can cause even more trouble than lung cancer since these patients live for many years in chronic sickness.

Each year in the UK 6,000 people die of bronchitis. It certainly is *not* smart to smoke. Patients cough, and produce varying amounts of sputum, or phlegm. They often wheeze like asthmatics. This may go on for many years before the right side of the heart begins to fail. Gradually, during this time, the chest tends to become barrel-shaped. Treatment consists of getting the patient to stop smoking or otherwise contaminating his lungs, preventing infection, particularly during winter months, with germ-killing antibiotics, and breathing exercises.

Smoking. Giving up smoking is a good idea at any stage. Using nicotine replacement gum, patches, or inhalers doubles the chance of successfully quitting. A nicotine-free drug, Zyban, is also available on prescription from your GP. There are also e-cigarettes. Set a day to stop smoking and reinforce your resolve by telling your family and friends, or getting someone to give up with you. The NHS has a Smoking helpline 0800 169 0 169.

Bronchial Asthma is a condition in which the finer air passages become constricted due to an allergic response. In addition, an increased secretion tends to obstruct them and the patient wheezes. In many cases it can be shown that he is allergic to a particular component of dust, or, less commonly, a foodstuff. This is the same sort of thing as occurs in the upper respiratory passages in hay fever, but the effect is on a different, lower part of the respiratory system. Many other cases are due to respiratory infection of some sort, probably combined with an allergy to the bacteria causing it. A predisposition to asthma is often inherited in faulty genes.

Once a patient has become asthmatic, attacks will be triggered off by such additional things as emotional stress, changes in temperature (particularly sudden cold), irritating fumes or smoke, and physical exertion. These are secondary factors, and although much of the treatment is concerned with them, it is unlikely that any of them is a sole cause of the condition. Treatment is directed at the relief of the breathing difficulty and of the wheezing, as well as the control of the causative factors. Many useful drugs are available to dilate the contracted air passages and reduce the obstructing secretions.

Asthma in children often improves as the patient grows up. Asthma is another condition made much worse by smoking. (*e.g.* by parents who smoke in the house). In 2008 an asthma jab (of the drug Xolair) received approval for NHS use for treatment of severe persistent allergic asthma. A new technique, *bronchial thermoplasty*, is also producing good results. It feeds hot air into the lungs. The outlook for new drugs and treatment received a major boost when scientists discovered that an *overactive calcium sensing receptor* causes much of the problem. In 2016 researchers developed an asthma pill hailed as a game changer.

A tiny living mite about 0·3 millimetres long exists in large numbers in nearly all mattresses and floor dust. This is the cause of much asthma.

The National Asthma Campaign has found that Britain has more asthma sufferers than any European country (and asthma is now our biggest childhood disease). The statistics are alarming. Over 5·4 million receive treatment (including around a million children) and 1,250 die each year in the UK.

Bronchiectasis. In this condition the bronchial air passages are abnormally and permanently dilated, and the normal structure of the walls destroyed. It is caused by obstructions of the tubes which lead to dilatation of the parts beyond. Secretions accumulate, and since they cannot easily drain away, they become infected. The infection helps to complete the process of destruction of structures in the bronchial wall. The patient has a chronic cough which often produces large quantities of purulent sputum, and there are often recurrent episodes of pneumonia. Diagnoses of bronchiectasis have risen over the last decade, especially among well-off women.

In some cases, where the disease is localised to one part of the lung, it is often a good idea to cut out that portion, and this is particularly true in young people. Vigorous physiotherapy, involving drainage of the lungs by placing the patient in a suitable posture, together with antibiotic drugs for the infection, are other forms of treatment.

Cystic Fibrosis is an inborn disease which affects chiefly the lungs and the digestive system. It is sometimes called *Fibrocystic disease of the Pancreas*, and sometimes "mucoviscidosis".

Today, cystic fibrosis is known to be the commonest genetically determined disorder affecting children in Britain. One child in 2,000 receives one of the abnormal genes from each parent. Such a child therefore has a double dose of the harmful gene, and will have the disease from birth. One person in 25 of the general population carries only one of these abnormal genes, and such an individual will not have the disease, but will be a carrier of the abnormal gene. If such a seemingly normal carrier marries another carrier, there is a one in four chance of each of their children being affected. The children, therefore, who actually develop cystic fibrosis have inherited the disease *equally* from both parents, who are carriers, but are themselves unaffected by the disease.

The disease is inherited recessively and involves a defect in pumping salt across cell membranes, particularly in glands. The prospects for survival into reasonably healthy adult life are steadily improving, but they depend upon early diagnosis and careful management through childhood. In cystic fibrosis most of the damage is caused by the excessive viscidity, or stickiness, of the mucus which is produced in the breathing tubes as a lubricant, and also in the ducts of the pancreatic gland which provides enzymes to help digestion. Being thick and sticky, instead of thin and slimy as in the normal, this mucus tends to block the passages instead of keeping them clear. The pancreatic cells are permanently destroyed. The gland cannot secrete pancreatic enzymes, and the food, especially protein and fat, is not properly absorbed. This deficiency can be compensated fairly well by giving pancreatic extract by mouth with every meal, and by dietary care.

The major clinical problem is in the lungs. The lung passages normally have a thin coating of mucus which is propelled steadily upwards, and is completely renewed in less than one hour. It moves more suddenly on coughing. In cystic fibrosis this upward movement is slowed down and interrupted. There is difficulty in keeping the passages clear, especially when infection with bacteria or viruses greatly increases the amount of mucus. This results in intermittent blocking of the air passages, difficulty in breathing, incomplete use of the lungs, and persistent local pockets of infection. If such infectious processes are not controlled, areas of lung will be destroyed, chronic infection will persist, and multiple lung cavities will develop. These predispose to further infection, interfering with the natural development of the lung—a process not normally complete until halfway through childhood—thus adding to the respiratory problems the child will face later.

Unless a correct diagnosis is made and proper treatment instituted before the first serious lung infection has occurred, the resulting lung damage may well be permanent. Compared to 20 years ago, the outlook for cystic fibrosis sufferers is continuing to improve. Gene therapy may open exciting possibilities. Life expectancy is increasing. Further information is available from the Cystic Fibrosis Trust, which provides help for the sufferers in the UK, who now number over 10,000.

Lung Transplantation can be done, using lungs from a donor who has died, or part of the lungs from each of two living donors. Half of lung transplant recipients are alive five years after surgery.

Pneumonia. This is an infection of the lung tissue, rather than of the air passages. The lung is the only internal organ which is directly exposed to the air, and since there are germs of all kinds in the air, it is a source of surprise that pneumonia is not a much more common event in all of us. The answer lies, as with all infections, in the fact that it is not simply bacteria which cause disease, but our own lack of resistance to them.

If we allow germs to thrive and multiply by being unhealthy or run down or undernourished, infective disease will occur. If we are fit, the entry of those same harmful germs into the body causes us no inconvenience, unless we are very young, or very old, or unless the invasion of germs is abnormally overwhelming. This helps to explain why pneumonia is so often quoted as a cause of death. In most cases it is merely a terminal event occurring in the elderly sick, whose normal resistance is so far reduced by their illness that they succumb to an invasion which they would normally not notice.

There are two main kinds of pneumonia, and in both the air sacs become filled with inflammatory secretions, making the normally porous lung tissue as solid as liver.

Types of Pneumonia. In *lobar pneumonia*, a whole segment (or lobe) of the lung becomes solid. In *bronchopneumonia*, areas of lung tissue surrounding the smaller bronchioles become consolidated, leaving normal porous lung tissue in between. Bronchopneumonia is the one which occurs in the rather stagnant lungs of people who are already ill or bedridden. Both forms respond to treatment with the appropriate antibiotics, provided any underlying debility does not interfere with the patient's own resistance. In the terminal bronchopneumonia of fatal illness, it is sometimes considered kinder not to treat the additional pneumonia. *Pleurisy* is a natural complication, and before the days of antibiotic drugs *lung abscess* was very much feared. For another form—*viral pneumonia—see* **Z10(2)**.

Pneumoconiosis. This is a term which refers to a large group of different diseases, all of which are caused by breathing in some form of dust over a very long period of time. It is therefore an occupational hazard of certain trades. We have already mentioned the mechanisms of mucus secretion in the air passages which normally trap small particles from the air, and prevent them reaching the lung. However, in some occupations there is so much dust breathed in over the months and years that these normal barriers are defeated. About a quarter of the earth's crust consists of silicon, in quartz, flint, or sand.

Silicosis occurs in people who have worked for many years in trades like mining, stone crushing, sandblasting, or metal grinding, who are often breathing silicon dust in high concentration. When the particles arrive in the air sacs, they set up an irritant chemical reaction which produces nodules of scar tissue. Silicosis for some reason predisposes to tuberculosis. Emphysema also occurs and there is a general impairment of respiratory function. Coalminer's pneumoconiosis is somewhat similar to silicosis.

Asbestosis. Asbestos is a complex silicate of magnesium, calcium, and iron. *Asbestosis* is caused by inhaling its fine fibres, and often leads to the appearance of a type of lung cancer called mesothelioma. *Berylliosis* is caused by compounds of beryllium, used in the manufacture of fluorescent lamps. *Farmer's lung* is a pneumoconiosis caused by inhaling hay and grain dust, and is similar to *bagassosis* and *byssinosis* caused by sugar cane and cotton dust respectively. *Mushroom worker's lung* is caused by something in the compost in which mushrooms are commercially grown.

Pulmonary Embolism. This very dangerous, yet quite common condition has already been briefly referred to (**Z30**(1)). It is a cause of tragic, sudden death in people who have had operations or have given birth to babies some days previously, or who have been bedridden for any other cause. The first event is that the blood in the veins of the legs becomes stagnant, due to the lack of exercise; and together with the tendency to clot which often follows surgery or childbirth, the whole length of a leg vein may be obstructed for twelve inches or more by an elongated clot of blood. This does little harm to the circulation of the leg, since there are plenty of other veins for returning blood to the heart. The danger is that the clot will become dislodged and be swept upwards towards the heart by the flow of returning blood. When this happens it is carried by way of the right atrium and ventricle into the pulmonary vessels which normally carry spent blood to the lungs. Here, for the first time, it enters vessels which are getting smaller as they divide, and it then impacts in the main pulmonary artery. The patient, who may have been recovering very well, suddenly collapses and not unusually dies there and then. At autopsy a long coiled-up mass of clot is found obstructing the pulmonary vessels. It often can be seen to form a cast of the leg vein and even bears the marks of the small venous valves which are present at its site of origin. With the dramatic advances being made in chest surgery, it is now sometimes possible in selected cases to operate to remove the clot. Thrombolysis, that is using injected drugs to dissolve clots, may also be used rather than pulmonary embolectomy. Three quarters of all cases of pulmonary embolism die within two hours, and therefore the best hope would be to prevent the occurrence altogether. This is not at present possible, but clotting in leg veins can be discouraged by early exercise following surgery and childbirth.

Patients often resent having to get up the next day because it is so uncomfortable. But it helps avoid pulmonary embolism.

Haemoptysis. This means coughing up blood or blood-stained material. It must be distinguished from *haematemesis*, in which the blood is vomited from the stomach. It must always be taken seriously because of the underlying lung disease which may be present. No one who coughs up blood, in however small a quantity, should neglect to inform their doctor so that its source can be determined. Haemoptysis occurs in a variety of lung disease, some of which is not serious but much of which must be treated immediately if it is not to become so. This is a suitable place to repeat our general rule that you should see your doctor without delay if you have any unexplained bleeding from any part of the body, however well you feel. And this includes haemoptysis.

Fat Embolism. Liquid fat sometimes enters the bloodstream following extensive crush injuries to soft tissue and bone. It splits up into millions of small globules which are carried to the lungs, and impact in small blood vessels there, producing obstruction of the lung circulation and consequent difficulties in breathing.

Lung Cancer. This is one of the commonest and at present most incurable forms of cancer which can occur. It is also probably the easiest to prevent. Each year many thousand people die of lung cancer in Great Britain. Although most are men, the toll among women has been rising fast. Scotland has one of the highest rates of the disease in the world.

There has been no reasonable doubt for very many years now that it is associated with cigarette smoking, and the evidence is overwhelming. However, in spite of this certain knowledge, smoking continues to increase, and every year there are more and more people dying unnecessarily of lung cancer (although it should be stressed not *all* lung cancer originates from smoking).

However, some recent encouraging evidence is emerging that the 50-year epidemic of lung cancer among women in Britain may be coming to an end. At the moment, however, women smokers are nearly 10 times more likely to die of lung cancer than in the 1960s.

Lung cancer grows in the wall of a main bronchial air passage. If it grows inwards it can obstruct the airway, choking that part of the lung it is supplying with air. This causes collapse and infection of the lung and may lead to *lung abscess*. The patient will then cough up blood-stained infected and purulent material. Such a case is comparatively lucky, since the disease declares itself early by producing symptoms. In others, the lump may grow outwards into the surrounding lung and produce no symptoms at all in the early stages. Indeed, it may spread to other parts of the body, like brain or bone or liver before causing any trouble to the patient. If this happens he may go to his doctor because of fits, changes of personality, or fracture, only to find that the origin of the trouble is in the lung. A gene that can lead to lung cancer in people who have never smoked was found in 2010. A blood test to detect early signs of lung cancer is being developed.

Cure rates are low, although much can be done to relieve the pain and suffering of the last stages of the illness. Survival rates vary from 16–53% at 5 years, depending on the type and severity of disease. Surgery, by removing the lung, and irradiation of the growth are the standard palliative treatment. A new test is now being used to identify lung cancer by detecting unique chemicals in the breath of those suffering from it.

It is not the practice of this Medical Section to alarm the reader unnecessarily, but if only a few are induced to stop giving themselves such a horrible disease, then writing in this way will have been justified. Readers may wish to see the note on **Z31** on giving up smoking. The dangers of e-cigarettes are not yet fully known.

Secondary Cancer of the Lung. In nearly all forms of cancer, the big problem is that it spreads to other parts of the body. If this were not so it could be eradicated by surgical removal more often than it is. One common way in which it spreads from any part of the body is by entering the bloodstream and being carried as clumps of living cancer cells to distant parts. When these come to rest in smaller blood vessels, they begin to grow and colonise the new environment. Such new colonies are called *secondary deposits* or *metastases*. It so happens that all veins (except portal veins of the liver) lead to the right heart and thence directly to the lungs, and for this reason the lungs are a very common site of *secondary* cancer, which may have begun in the bowel, or breast, or indeed anywhere else in the body.

Other common sites of secondary, blood-borne cancer are the brain, liver, bone marrow, and kidney, since all of them have an abundant blood supply, and there is therefore a high chance of the travelling cells arriving there. Secondary cancer of the lung usually consists of several lumps scattered throughout the lung. Lung cancer itself is usually only one growth. One of the main reasons for the success of early diagnosis is that treatment may be possible before blood-borne and other means of spread have occurred. Unfortunately, in the case of primary cancer of the lung, even early diagnosis is of little avail, but in many other common cancers permanent cure is possible if treatment is begun early enough.

Pleurisy. The chest is lined by one layer of a thin membrane called the *pleura*. The lungs are covered and enclosed by a second, continuous layer of this same membrane. When the lungs move during respiration, the pleura covering the lungs rubs against the pleura lining the chest, lubricated by a very thin layer of pleural fluid separating the two pleura. Whenever the pleural surface becomes inflamed, this is known as *pleurisy*. It is nearly always due to inflammatory disease of the adjoining lung, and is therefore not strictly a disease in its own right.

For example, pneumonia, tuberculosis, lung cancer, or a lung infarct will produce a pleurisy if the area of diseased lung adjoins the lung surface. Some-times the area of inflamed inner pleura will tend to stick to its outer layer or rub painfully against it, producing a sharp pain when the patient breathes.

Sometimes a large effusion of fluid is produced which separates the two layers and collapses the lung by occupying space in the chest which the lung should be occupying. This latter is more usual in tuberculosis or cancer.

The lung can be collapsed by the entry of anything between the normally adjacent layers of pleura, for example by accidental rupture of the lung with emphysema (*q.v.*). This condition is called *pneumothorax* or "air in the chest." Bleeding into the cavity between the pleura is called *haemothorax*.

THE DIGESTIVE TRACT AND LARGE INTESTINE.

Introduction.

The digestive tract consists of the mouth, pharynx, oesophagus (or gullet), stomach, small intestine, large intestine (or colon), rectum, and anus. The small intestine is very long, and is subdivided into the duodenum, jejunum, and ileum. It ends at the junction of the ileum with the caecum, where there is a small blind side-tube, the appendix. The caecum leads into the colon. The whole tract has two main mechanical functions and two main biochemical ones. Mechanically, food has to be chewed in the mouth and further minced up by muscular squeezing, mainly by the stomach. It has also to be propelled along by an orderly series of squeezing movements known as *peristalsis*. While it is still in the digestive tract, food has to be digested. That is to say, it has to be broken down chemically into suitable materials for absorption into the system, and secondly, it has to be absorbed across the wall of the intestine into the blood stream, itself a highly complex biochemical process. The blood stream it now enters is a special part of the circulation, the "portal" system, which travels directly to the liver without first passing to the heart. In the liver the broken-down foods are processed and issued in their new form into the general, or "systemic" circulation, by which they are finally carried to all the tissues of the body.

Alimentary Canal. As the food passes along the digestive tract (or alimentary canal), it is mixed with various secretions which are either made in the wall of the tract, or by organs outside the wall connected to the main pathway by small tubes. Examples of the latter are bile, manufactured by the liver and sent into the duodenum through the bile ducts; and pancreatic juice, which comes from the pancreas down the pancreatic ducts, also into the duodenum. These secretions are either digestive juices concerned with splitting up the foodstuffs so that they can be absorbed, or they have a lubricant so that the gut contents slide along easily under the influence of peristalsis. Roughly speaking, it may be said that digestive juices give place to lubricant secretions at the junction between the small and large intestine.

The Digestive Process.

The constituents of the diet are dealt with in a later section. The principal classes with whose digestion we are now concerned are carbohydrates, proteins, and fats.

(i) **Carbohydrates** are sugars and starches. There are many sugars, which may exist alone, in pairs, or with lots of them stuck together. Alone they are such things as glucose or fructose. Common table sugar is a substance called sucrose, formed by sticking one glucose molecule to one fructose molecule. Starch is lots of glucose molecules all stuck together. Digestion of carbohydrates consists of splitting up sugars and starch into single sugars like glucose, since only single sugars can be absorbed into the system. The splitting is done by digestive *enzymes* which are found in the juices secreted into the digestive tract. Sugar-splitters are found in the saliva of the mouth, in the pancreatic juice of the duodenum, and in the duodenum's own juice from its own wall. On the face of it, you might think it would be better to eat glucose which needs no digestion and can be absorbed in this form, than to eat starch which has first to be split; and so a lot of money has been made out of a gullible public by the sale of glucose drinks and powder. In fact digesting starch is no problem whatever, even for the sick, who can obtain their carbohydrate energy just as easily (and much more cheaply) from potatoes as from expensive glucose. The end result of eating both is the same. The starch-splitting enzyme in saliva is mixed with the food as it is chewed, and it is therefore probably a good idea to chew it well. However, even if the food is bolted it does not seem to matter very much. People without teeth (neither their own nor dentures) seem to digest their carbohydrate quite well, presumably by means of their pancreatic juice at a later stage.

(ii) **Proteins**, which are found in meat, cheese, and eggs, are very large molecules consisting of lots of small ones strung together. Unlike starch, in which all the component glucose molecules are identical, the amino acids of which proteins are composed come in many different types. They all contain nitrogen, and there are about twenty-seven varieties. One protein differs from another in the proportions of the mixture and the order in which they are stuck together. Only single amino acids can be absorbed from the food, and so protein digestion again consists of splitting the material down into its building bricks. There is a strong protein-splitting enzyme in the gastric (or stomach) juice called pepsin, whose job it is to split the long amino-acid chains into shorter chains. Several other protein-splitters in the duodenal and pancreatic juice contrive to break the smaller chains into individual amino acids which are then absorbed and sent to the liver for processing.

(iii) **Fats** mainly consist of glycerol to which are attached three fatty acid molecules for each molecule of glycerol. An enzyme in pancreatic juice splits the fatty acids off the glycerol, but would have some difficulty penetrating the globules of fat without the help of bile. One of the constituents of bile (bile salts) has detergent properties like washing-up powder and breaks the fat globules up into a very fine emulsion so that the enzyme can get at the fat. Some fat particles of this size can even be absorbed as such, without preliminary splitting.

The processes by which all these enzymic secretions are produced are very finely controlled. They are very expensive to make in terms of energy and raw materials, and so it would be very wasteful to produce them all the time, even when there was no food to digest. And so the body has some very well designed automatic arrangements for sampling the foods as they are eaten and passed on, which ensure that exactly the right kind of juice is waiting in every part of the digestive tract for whatever food arrives. As soon as the food is digested the supply of enzymes is automatically switched off, so that there is very little waste of precious materials. It is, of course, beyond the scope of this account to describe the control mechanisms. Suffice it to say that they are operated partly by nerve reflexes which signal the imminent arrival of food, and partly by special hormones produced in various parts of the gut wall.

The best secretion is affected even by psychological factors, so that pleasant company and surroundings, attractive appearance of the food, and an eager anticipation of it all make for good digestion and good health. These psychological factors are all capable of proper scientific investigation and proof. The poor health of those who habitually and irregularly bolt unpalatable food is probably due to such factors as these. So is the failure of appetite in the depressed, the anxious adult, or the scolded child.

Nearly all the digestion which has been described occurs in the stomach and upper part of the small intestine (the duodenum, jejunum, and upper ileum). Almost all absorption of the products of digestion occurs in the small intestine which is long and intricately folded to give it a large surface area for this purpose. The colon, or large intestine, is adapted for conserving water, by removing it from the residual waste material. This has then to be eliminated, and being rather dry its passage has to be lubricated by suitable secretions of mucus.

Constipation. For some people it is entirely normal only to pass motions about once or twice a week. For others the normal frequency is once or twice a day. What is abnormal? The answer is that the only thing worth worrying about is pronounced change of bowel habit, particularly in middle-aged and older people. By a change is meant a change from that individual person's normal routine. Such a pronounced change—either in the direction of constipation or diarrhoea—is worth consulting your doctor about if it persists for more than a week or two.

Constipation should be treated first by diet containing plenty of roughage—bran and oatmeal are excellent—plenty of stewed and fresh fruits, and at least 1½ litres of fluid should be taken daily. Failing that take a proprietary product prepared from senna pods. Never to be taken regularly are liquid paraffin, castor oil *etc*.

Oesophagus.

The oesophagus, or gullet, is more than a simple tube for taking the food from the mouth to the stomach. It is normally closed except when swallowing, and the act of swallowing is very complicated. When the material to be swallowed arrives in the back of the throat there is an automatic mechanism which opens the top end of the oesophagus to receive it, and from then onwards everything happens automatically. The next portion of the tube opens and the top closes strongly, so that the food (or drink) is propelled forcibly down the next segment. Then the part below this relaxes and the material is squeezed further downwards and so on until it arrives in the stomach.

This squeezing (or milking) action is similar to the action known as peristalsis which propels contents in other parts of the gut. Thus when you see someone swallowing a glass of beer very quickly in warm weather, it is not going "down the hatch" under the influence of gravity, however much it may look like it. It is perfectly possible to swallow the same, or any other liquid, standing on your head. Getting into that position is the only difficult part. Sometimes this complicated swallowing mechanism gets out of order, leading to difficulties of swallowing, or *dysphagia*.

Hiatus Hernia. Another disorder known as *hiatus hernia* occurs at the lower end of the oesophagus as it meets the stomach. At this point the oesophagus has to pass through the diaphragm, the sheet of muscle which separates the chest from the abdomen. The muscular fibres of the diaphragm are normally arranged in a ring around the oesophagus. These help to keep the lower end shut, so that the acid contents of the stomach do not regurgitate upwards, causing inflammation (*oesophagitis*) or heartburn. A hiatus hernia is when muscle fibres get slack, and the upper end of the stomach can even slide upwards into the chest. People with hiatus hernia get heartburn after meals, and particularly when they bend down or lie down. Except for very severe forms, which need surgical repair, the treatment is to eat less at a time, reduce the acidity with a suitable antacid and reduce weight so that the weight of the abdomen does not press upwards so much.

Cancer of the Oesophagus.

The other disease of the oesophagus, quite unrelated to the above, is *cancer of the oesophagus*, the cause of which is still unknown in most cases. When cancer occurs in the wall of any tube, it will often encircle the tube and gradually narrow the way through. This is what happens in the oesophagus, leading to difficulty in swallowing, particularly solids. It is a condition usually, of rather elderly men, although it is sometimes associated with a special form of severe anaemia in women.

Treatment is to keep the passage open, either by transplanting a new tube, or more usually, by removing the constricted piece and joining up the remainder.

Britain has the highest levels of this cancer in Europe and there may well be a link to rising obesity levels. Cases of this cancer in men more than doubled in Britain between 1985 and 2015. The toll is still rising with *c*. 8,500 new cases each year.

A fluorescent "throat spray" highlighting abnormal cells can help doctors detect the disease earlier.

The Stomach and Duodenum.

By far the commonest diseases of the stomach and duodenum are *gastric ulcer* and *duodenal ulcer*. They are actually the same condition in two different sites and are often classed together as *peptic ulcer* or *acid-peptic disease*. The ulcers, which are rather like sores on the lining of the stomach or duodenum, may be "acute" or "chronic." Acute ulcers tend to be small and there are often several of them. Chronic ulcers are usually single. They may be small, or they may be several centimetres across. Chronic ulcers smoulder for months and even years, like a sore which will not heal, and a great deal of scar tissue forms in their depths. Thus they may in time erode their way right through the wall of the stomach, destroying all its layers, and begin to eat into surrounding structures like the pancreas or liver. The fact that they do not perforate more frequently is due to all the fibrous scar tissue which is formed during the slow eroding process. Healing of such a destructive ulcer is nevertheless common, and the great problem is how to help the natural healing process to win against the ulcer's tendency to erode.

Treatment of Ulcers.

Ulcers are very commonly associated with the bacterium Helicobacter pylori, which may be the cause of ulcers. Appropriate treatment to eradicate this organism is an important part of ulcer therapy. This extremely common affliction is confined to the human species and has been known since the earliest times. It does not vary very much with diet or with social class. Although occurring at all ages, it usually begins between the ages of twenty and forty, and is most commonly found in men between forty-five and fifty-five. Gastric ulcer is four times, and duodenal ulcer ten times more common in men than in women. It is always due to an inability of the lining to stand up to the normal digestive activity of the stomach contents. These are normally acid and contain a powerful enzyme for digesting proteins. Again it is perhaps more surprising that we all do not digest our own stomachs, rather than that some unfortunate people do digest small areas slowly. In certain abnormal conditions when the stomach stops making acid, ulcers always heal. However, some ulcers occur without excessive secretion of acid and many heal without the acid being neutralised with antacids.

Symptoms of Peptic Ulcers.

All this points to the main trouble being in the response of the lining to acid rather than to the acid itself. Nevertheless, the most effective treatment at present known involves regulating gastric secretion, and particularly its acidity. It is also known that peptic ulcers are more common in people whose occupations involve administrative and professional responsibility, competitive effort and nervous tension, long periods of anxiety or frustration. Presumably the higher nervous system influences these events by the same nerves, which normally help to control secretion.

The main symptom of peptic ulcer is pain, and this usually responds well to proper doses of antacids. Many different varieties are available and a lot of money is made from selling them. When indigestion persists for longer than a few days it is always better to see your doctor so that a proper diagnosis can be made and the best remedies begun. Many other causes exist for similar pains, and you should not try to make the diagnosis yourself. It may be necessary to analyse your gastric secretions in the hospital laboratory. Almost certainly you will have a special X-ray examination, and since the stomach cannot easily be seen on a normal X-ray, they will have to show it up by making you drink a white material containing barium. This will be seen as a silhouette of the stomach and duodenal contents. Searching for an ulcer this way is a highly skilled matter and is performed by doctors specially trained in radiology.

Until recently, no drugs capable of influencing the course of peptic ulcer in any significant manner were available and the physician had to rely on general measures, such as rest, diet and the administration of antacids to relieve pain and discomfort: episodes of acute haemorrhage were not uncommon and required surgical intervention.

Endoscopic Investigation. Most ulceration in the stomach and all in the duodenum is due to bacterial infection, *Helicobacter Pylori*. This damages the intestinal wall and makes damage from the stomach's own acid inevitable. Eradication cures the disease, although re-infection may occur. The gastroenterologist can now pass a *flexible* instrument, the *gastroduodenal endoscope* (the gastroscope is a *rigid* tube), under mild sedation through the patient's gullet and into the stomach and duodenum and view the lesions directly. Once an ulcer is diagnosed, the time has come to stop treating yourself with antacids from the chemist's counter, and to take the ones your doctor decides are best. Smoking should be stopped by ulcer patients because it inhibits healing.

Alcohol tends to increase acid secretion and should be avoided. It is also *extremely important* to avoid taking any form of aspirin, even in quite small amounts, since this can lead to very serious bleeding from the ulcer. The ulcer patient should be warned that hundreds of proprietary preparations contain aspirin and all of them are dangerous for him. Search for the formula in small print on the label before taking any remedy, looking particularly for acetylsalicylic acid the systematic name for aspirin. Some of the patients with "upset stomach" are, of course, ulcer patients, and some even die of haemorrhage following the ingestion of aspirin.

Complications of Peptic Ulcers.

The main complications of peptic ulcer are bleeding, perforation, and a narrowing of the pylorus, or lower part of the stomach (*pyloric stenosis*). Bleeding is caused by the eroding ulcer eating away at one of the many blood vessels in the stomach or duodenal wall. It leads to the passing of "altered" blood in the stool (*melaena*), or to the vomiting of blood (*haematemesis*). When the initial bleeding occurs, the patient may feel suddenly faint, and a little later will notice the black, tarry colour of his stool. This is sometimes confused with a similiar colour when the patient is taking iron. Peptic ulcer is not the only cause of this very serious haemorrhage, which constitutes a hospital emergency whatever its cause. The treatment, like that of every large haemorrhage, is blood transfusion which must be continued until the bleeding stops, or until the patient is sufficiently fit for surgery, should that be needed.

Perforation is perhaps the most serious complication of peptic ulcer, leading to the spilling of stomach contents within the abdominal cavity. Treatment is invariably surgical, either the closure of the perforation or the partial removal of the stomach.

Surgical removal of part of the stomach is often the only way to treat a peptic ulcer which has had its chance to heal in other ways. It is tempting for the patient to "have it out and done with," but the time for surgery is a matter of fine judgment. So many ulcers heal by medical means if given a chance, and operations are for those which persistently refuse, or are complicated.

Stomach Cancer. The stomach is a fairly common site for primary cancer. There is no known reason for this, and it is particularly important to stress that we know of no connection whatever between the peptic ulcers which have just been discussed and cancer. Stomach cancer used to be the commonest cancer of men, but the current rise of lung cancer has pushed it into second place. There are some strange geographical differences in its distribution. For example, it is much commoner in Japan and Scandinavia than in England or the USA. It is difficult to see any reason for this in dietary habits. In Wales it causes three times as many deaths as in South-East England. All this is very puzzling, as is so much of our information about cancer generally. One of the main problems with stomach cancer is that it often causes the patient no inconvenience and thus produces no symptoms of note until the disease is far advanced and is difficult to treat.

Treatment is by the surgical removal of the growth, and even in the most advanced cases a great deal can often be done to make the patient more comfortable.

Recently doctors have reported evidence of a link between alcohol, eating processed meat and being overweight and suffering from stomach cancer. The risk of stomach cancer is 1 in 64 for men and 1 in 92 for women in the UK.

The Small Intestine.

The small intestine runs from the stomach to the caecum and comprises the duodenum, jejunum, and ileum in that order. On a more cheerful note it may be remarked that it is very rarely the site of cancer. Its main problems arise in connection with defects in absorption mechanisms, with obstructions, and with a strange inflammatory condition known as *regional enteritis*. Most obstructions are due not to blockages of the tube, but to failures of peristaltic propulsion, the process which is briefly described above under "oesophagus." Such a failure is called *ileus*. When peristalsis stops for any reason, the result is severe dehydration and loss of important chemicals like sodium and chloride from the body. This is because about 9 litres of fluid enter the small intestine each day in the form of digestive juices, and all of this has to be pushed onwards to be reabsorbed into the system at lower levels. If peristalsis fails, this bulk of fluid remains in the small intestine, or is vomited. In both cases it is lost to the body itself, leading to serious dehydration and illness. Treatment is by very careful replacement by transfusion of the fluid and the chemicals lost, and by removal of the trapped fluid within the intestine through a tube threaded down through the mouth.

Regional Enteritis or **Ileitis** is very often known as **Crohn's Disease**. It is a very debilitating condition in which the normally supple wall of the small intestine becomes inflamed and gradually replaced by thick fibrous scar tissue, so that it looks and feels like a thick garden hose. Loops of inflamed gut stick together, and channels open between them, and if the disease progresses a mass of adherent, thickened intestine results to which everything in the neighbourhood also adheres.

However, for some unknown reason some cases do not progress downhill in this way and get better spontaneously. Surgical treatment is necessary for the majority, however, particularly those with advanced disease leading to complications such as obstruction or perforation. Sometimes an early case can be resolved by cutting out the length of affected gut, although recurrences are unfortunately common. A genetic link between Crohn's disease and childhood asthma has now been found. A move is underway to provide special hospital meals for Crohn's disease patients.

Recently a link has been suggested between the upsurge of cases in the USA among women and the explosion in the use of oral contraceptives.

Appendicitis. This must be one of the best-known surgical diseases of the intestinal tract. The appendix is a narrow, blind-ended side tube attached to the caecum near the end of the small intestine, Appendicitis is when it becomes obstructed, or infected, or both. From its position it is almost predictable that it will get obstructed sooner or later by pieces of faecal matter which pass its entrance and which are normally infected. The surprising thing is that it does not happen more often. Once this has occurred, however, a closed abscess forms, and as the abscess distends the appendix, it first weakens its wall, making it gangrenous, and then bursts into the abdominal cavity causing *peritonitis* (*see later*). It would be useless and misleading to describe the symptoms of acute appendicitis in detail, since it is difficult even for experienced doctors to distinguish them from those of several other conditions. Suffice it to say that any severe, persisting pain in the abdomen, whether continuous or intermittent, whether associated with diarrhoea or not, should lead the sufferer to a doctor for a quick diagnosis. Germ-killing antibiotics are useless against appendicitis, and any laxative is extremely dangerous as it may cause an acutely inflamed appendix to perforate.

The Large Intestine or Colon.

The two main serious diseases of the colon are ulcerative colitis and cancer in its various forms.

Ulcerative Colitis is yet another mysterious disease in which severe ulceration of the lining of the colon gives rise most frequently to diarrhoea with the passage of blood and mucus. In fact it can be like dysentery, and it has often been considered to be due to some form of infection. Unfortunately no particular germ can routinely be found in these cases, and the situation is endlessly confused by the presence in the normal bowel of lots of different germs anyway. Nevertheless the ulcerated lining of the bowel certainly does get infected by the germs normally present, and this makes the disease worse. Therefore germ-killing antibiotics are often helpful in alleviating symptoms and can lead to an earlier settling down of the condition, although not to a cure. It has long been known that certain kinds of psychological upset are often associated, but here again the disease is so unpleasant for the sufferer that he is to be forgiven some despondency as a result of, rather than as a cause of, his troubles. It is also suspected that ulcerative colitis may be an auto-immune disease; that is it may represent rejection by the patient of his own colonic lining in a manner somewhat comparable to the tissue rejection which often follows organ transplantation.

Some of the more awkward complications are perforation through the wall of the ulcerated bowel, and sometimes massive haemorrhage occurs. Treatment is with sulphasalazine or drugs derived from it, together with diet and the occasional use of other drugs to minimise symptoms. Surgery may be required to relieve obstruction, deal with perforation, remove affected parts of the bowel, *etc*.

Bowel Cancer (Cancer of the Colon and Rectum). This is another very common form of cancer, which can often be completely cured by surgical removal of the growth provided it is caught in the early stages before it has spread. The commonest symptom is a change in bowel habit, either towards constipation or, more often, towards diarrhoea, in the second half of life. There may be rectal bleeding, or the passage of mucus, and there may be abdominal pain. We cannot too often repeat that any such change of bowel habit, or any unexplained bleeding, should lead the patient promptly to his or her doctor.

Bowel cancer is the fourth most common cause of cancer death in the UK (most deaths occur when cancer spreads to the liver). A landmark study published in 2016 revealed more genetic links to bowel cancer. Cases are also rising. Today a major NHS Bowel Cancer Screening Programme is underway. In 2009 a new technique to identify aggressive bowel cancers was developed.

Diverticulitis. Some people have small pockets or sacs in the wall of the colon known as diverticula. A minority of these sometimes get inflamed, and this is *diverticulitis*. Occasionally perforation occurs. When diverticula are present in the colon but not inflamed, the condition is known as *diverticulosis*.

Hernia or Rupture. This is a condition in which abdominal contents, usually a loop of intestine, protrude forwards through the muscular wall of the abdomen. The wall consists of a sheet of muscle fibres running in several directions. They normally become tense when we cough, or strain, or in getting up from a recumbent position. There are places in the groin on each side where there is a way through the muscle for the spermatic cord in the male. In many men a weakness can arise at this point, and if it persists, the way through may enlarge and allow loops of bowel to emerge from behind the muscle sheet to appear as a lump under the skin of the groin. On relaxation the lump can be made to disappear by pushing the contents back the way they came; and they will re-emerge when the patient strains. This is an extremely common complaint in men, and it should be treated by an operation in which the muscle wall is repaired.

Strangulated Hernia is the term used when the muscle tightens around the neck of the protruding loop of bowel, cutting off its blood supply. From then onwards the loop becomes gangrenous and the intestine is obstructed by having a part of itself nipped outside the abdominal wall. The patient is in severe pain, vomits continuously, and quickly is liable to get into such a poor condition that surgical relief is difficult. It is therefore a surgical emergency, and it would have been better to have had the relatively simple repair operation earlier and at leisure. Hernia in the region of the groin is of two types: *inguinal hernia* and *femoral hernia*, the difference between them being technical and of no consequence to the patient. They nearly always occur in men.

Incisional Hernia is when the muscle wall has been weakened at the site of an old abdominal operation and has failed to heal properly.

Umbilical Hernia occurs owing to the natural weakness of the abdominal wall at the navel, and is so common in babies as to be almost normal. When a baby cries and thereby puts a strain on his abdominal wall, a lump often appears in the region of the navel, and this can be very alarming for the parents. They should of course show it to their doctor who will nearly always be able to reassure them. It is self-healing without operation in the majority of cases.

Peritonitis. The cavity of the abdomen in which the intestines and other organs lie is called the peritoneal cavity, and it is lined by a thin membrane called the peritoneum. When this becomes inflamed the condition is a serious one and is called *peritonitis*. Inflammation may be bacterial, as occurs following a burst appendix and the spillage of bacteria and pus in the cavity. It may be a sterile peritonitis as often follows perforation of a peptic ulcer, when the inflammation is caused by the acid contents of the stomach. It is always very dangerous, probably because of the large surface area afforded by the peritoneum for the absorption of inflammatory toxins.

Haemorrhoids are simply varicose veins in the rectal and anal regions. They are very common, and are caused probably in about equal degrees by inherited weakness of the veins, strain such as heavy lifting, and constipation (this is one of the very few conditions in which constipation may do some damage, due to the mechanical pressure of hardened faeces in the rectum on the veins).

Pregnant women may develop haemorrhoids or "*piles*," as they are commonly called, owing to the pressure of the baby's head in the pelvis.

Haemorrhoids may be external or internal, the former being in the anal region below the sphincter, the latter in the rectum; the two usually go together. There may be no symptoms, but the veins are liable to bleed, to get thrombosed (*i.e.*, a clot forms within) or to become infected. When clotting or infection occurs the piles enlarge and tend to be pushed out through the anus during defaecation, when they form extremely painful external swellings. Treatment in simple cases may be by the use of suppositories—cones of a firm grease containing suitable medicaments which are inserted in the rectum—in other cases the veins may be injected, as with varicose veins of the leg, in order to close them, but when there is bleeding, thrombosis, infection, or interference with the bowels they should be removed surgically.

THE LIVER.

The liver is a very large organ and has such a wide variety of known functions (to say nothing of the unknown) that it is also one of the most complicated. Nearly all of its functions are biochemical, and it is often called the laboratory of the body. Thus the liver makes proteins from the amino-acids absorbed from the gut, and breaks down amino-acids and manufactures a waste product (urea) from them.

The liver stores carbohydrates as glycogen, and conducts many of the processes necessary to turn carbohydrates into energy. It manufactures prothrombin with the help of vitamin K, and this is essential for blood clotting. It makes bile and secretes it into the gall bladder and bile ducts (*see later*). The three main constituents of bile (cholesterol, bile pigment or bilirubin, and bile acids) all have to be processed, or metabolised, in the liver during the production of bile. Vitamin B_{12} and iron are also stored and dealt with there, and these are involved in preventing various forms of anæmia.

In addition to all these things the liver is the place where harmful substances, both from within the body and from outside it, are dealt with and rendered harmless. This last function of "detoxication" is often accomplished by making the offending molecules suitable for rapid excretion by the kidneys, or by altering their chemical shape to make them harmless.

For further information readers may wish to consult www.britishlivertrust.org.uk

Liver Cells. Nearly all of these very different things are done by one single type of cell: the liver cell, and it is one of the remarkable features of the design that this cell can be so versatile. There also have to be some very efficient transport systems in the liver, in addition to the usual blood supply and venous drainage possessed by all other tissues.

Fully functioning liver cells have now been produced from artificially created stem cells, offering new hope for people with liver disease.

The Portal Venous System.

One of these is the "portal venous system." Whenever a substance is absorbed across the gut wall from any part of the intestine into the interior of the body it enters the special draining blood vessels of the portal system, which are arranged throughout the length of the digestive tract. All these veins eventually unite in the main portal vein which enters the liver. Everything absorbed from the gut is therefore taken first to the liver to be processed. After this the products are carried away from the liver in the ordinary veins to the heart, and are distributed to the rest of the body by the arterial system. The liver has arteries of its own by which it receives oxygen and nutriment like any other tissue. The fourth transport system collects the bile as it is formed within the liver and delivers it to the gall bladder and bile ducts, which eventually drain it into the duodenum.

Portal Hypertension means high blood pressure in the portal venous system, and is the usual accompaniment to *cirrhosis* (*see later*). When the terminations of the portal veins in the liver are strangled and obstructed by cirrhotic disease, this tends to blow them up, or dilate them with blood. There is a natural escape route for the portal blood where the lower end of the oesophagus or gullet joins the upper end of the stomach. At this place some of the portal veins draining the stomach are connected with the ordinary veins draining the oesophagus so that when pressure rises in the portal system, blood tends to be diverted into these connecting veins, and they in turn become dilated, or varicose. Trouble begins when these dilated connecting veins, which bulge inwards into the oesophagus, are damaged by food particles passing across them and bleed severely into the stomach. The patient vomits large quantities of blood (*haematemesis*) or passes tarry altered blood in the stool (*melaena*). The other main cause of these is the bleeding which may accompany peptic ulcer (*q.v.*).

Ascites is a second complication of portal hypertension (and hence of cirrhosis). Large amounts of a lymph-like fluid accumulate in the abdominal cavity. The fluid contains a great deal of precious protein and salt which is lost to the body economy. Ascites also sometimes accompanies cancerous deposits in the abdomen.

Jaundice means being yellow because there is too much yellow bile pigment circulating in the blood, and there are three main possible causes for this.

Bile pigment comes from broken-down red blood cells, which normally come to the end of their time after existing for about 120 days. The breakdown products of red cells can always be found in the blood of normal people, but there is normally insufficient colour to show. Abnormal amounts of colour build up quite logically in any of the following three circumstances:

(1) **Haemolytic Jaundice.** If too many red cells are being destroyed and even the normal liver cannot deal with the amount of bile pigment produced, it piles up in the blood, and haemolytic jaundice is the result. The expression simply means jaundice due to (abnormally large) red-cell destruction.

(2) **Hepatocellular Jaundice.** If the liver cells are themselves sick and unable to cope even with the normal amounts of pigment from normal red-cell destruction. Here too the pigment will pile up and cause hepatocellular jaundice, or liver-cell jaundice.

(3) **Obstructive Jaundice.** If the bile ducts carrying bile away from the liver are blocked, then bile will pile up behind the blockage and re-enter the blood stream, causing obstructive jaundice. In this case the rate of red-cell breakdown is normal, and the liver cells are normal: at least for a time.

It is enormously important for the treatment of jaundice for the doctor to diagnose its type correctly, since the treatment varies from surgical relief of obstruction to the medical treatment of viral infection or of excess red-cell destruction.

The so-called differential diagnosis of jaundice is often exceptionally difficult, and sometimes requires some very sophisticated laboratory tests and X-rays. At other times it is extremely easy and is obvious from a cursory glance at the urine and the stool. All jaundice is a highly technical matter.

Neonatal Jaundice. There is a special jaundice of newborn babies which resembles haemolytic jaundice and can occasionally have serious consequences for the developing brain (*kernicterus*) if it is allowed to become too severe. When this is threatened, steps are taken to reduce the level of circulating bile pigment by replacement of the baby's blood *etc.*

The commonest cause of hepatocellular jaundice is infective or viral hepatitis. Obstructive jaundice is usually due either to blockage by gallstones (*q.v.*) or by a lump pressing on the bile ducts from an adjacent cancer. This can often be quite satisfactorily relieved by surgery.

Infective Hepatitis. *See* **Z10(1)**.

Cirrhosis. There are many different kinds of cirrhosis, the commonest of which has already been mentioned under *portal hypertension* above. In all cases, liver cells are slowly poisoned and are killed off over a long period of time. In response to this, the surviving liver cells undergo cell division, trying to make good the numbers lost, and at the same time fibrous scar tissue replaces the damaged tissue throughout the organ. The result is a hard, knobbly liver. The many "knobs" are spherical areas of regenerated new cells, and they are separated by thickened bands of scar tissue. All of this destroys the normal architecture and leads to the portal hypertension and ascites mentioned above. In some countries (*e.g.*, France and the United States) excessive alcohol is the main cause of the original liver damage which starts it all off. In others (*e.g.*, South Africa) it seems to be nutritional starvation of the liver. In England much less than half the cases are due to alcohol, and many are thought to be due to a previous episode of infective hepatitis (*q.v.*), but this is not certain. The number of cases of cirrhosis in the UK more than doubled in the ten years to 2010 and alcohol is being blamed. The term "fatty liver" is used when the liver is showing signs of excess alcohol or other problems.

Infective hepatitis is quite common but cirrhosis was comparatively rare. However, excessive alcohol consumption caused deaths from cirrhosis to rise 7-fold from the 1960s to the 1990s (and they are still rising). The worst affected area is the north of England. One treatment for advanced cirrhosis is to replace the liver by transplantation. Live liver transplants began in the UK in 2006.

Cancer of the Liver. Cancer of the liver is quite common, but it is nearly always cancer which has spread in the blood stream from other parts of the body. The liver is a favourite site for such secondary deposits, since it has a large blood supply and will receive a generous helping of anything being carried. It is also a very "fertile soil" for the cancer seedlings to grow in. Primary cancer of the liver, linked to obesity and alcohol, trebled in the 30 years to 2009. Rates for liver cancer in women rose 60% in the last decade.

Gallstones. These are "stones" formed by some of the major constituents of bile coming out of solution and forming solid bodies. They are very common, and often cause no trouble at all. When they do, it is usually a colicky intermittent severe pain. This is due to the muscular walls of the bile passages contracting in an effort to expel an obstructing stone into the duodenum. The second common trouble arising from gallstones is obstructive jaundice, described above. It is small consolation to gallstone sufferers that the stones are often very pretty. If they contain calcium they will be visible on an X-ray. Otherwise they are not seen. Stones often occur in conjunction with inflammation of the gall bladder, known as *cholecystitis*. The treatment for gallstones is to remove them surgically together with the gall bladder if they are causing persistent symptoms. Also, a flexible endoscope can be passed into the intestine and a tiny wire basket passed from it into the bile system to remove stones. Operations are done by keyhole surgery.

The Pancreas is a soft, elongated gland lying behind the stomach; it is *c.* 12·5 cm long and 5 cm wide. Within its tissues lies the duct, which, when it leaves the pancreas, passes into the duodenum near the point of entry of the bile-duct. This duct transmits the juices containing enzymes which aid in the digestion in the small intestine. The pancreas, however, has two main functions: not only does it manufacture these important digestive juices, but in certain specialised areas, the islets of Langerhans, it makes insulin, the hormone which makes it possible for the body to utilise sugar.

Diabetes Mellitus (or ordinary diabetes) is a chronic disorder usually caused by a deficient secretion of insulin. The unused sugar accumulates in the blood and acts as a poison, which, in extreme cases, sends the patient into coma and may—indeed, in former times, usually did—result in death. The treatment of diabetes was revolutionised by the discovery of the hormone insulin by Banting and Best in 1921. On the whole, diabetes is more severe in young people than in the elderly, but with correct treatment it is possible for all cases to lead a perfectly normal life except for dietary restrictions and insulin injections. Not to be confused with *Diabetes insipidus* (*q.v.*). The main problem with diabetes mellitus now is that the wrong (albeit slightly) blood sugar levels that are found even with good therapy eventually damage small blood vessels, leading to problems with the eyes, peripheral nerves and kidneys. Everyone should ask their GP to test their blood sugar levels regularly.

Globally, cases of diabetes have grown from 153 million in 1980 to over 370 million today. In Britain there are 3·8 million diagnosed cases (expected to rise to 5 million by 2025). It is much more common among ethnic minorities. Diabetes is now one of the great health challenges of our age and urgent research is looking for a cure (or at least a reversal of the condition).

Hypoglycaemia, or low blood sugar (glucose), is something that can be a daily fear for many people living with diabetes. It is most commonly experienced by people with Type 1 diabetes who are unable to produce any insulin. It can also occur in people with Type 2 diabetes who are taking certain diabetes tablets and/or insulin. Hypoglycaemia (or 'hypo') occurs when glucose levels fall too low.

Pancreatitis is a condition where the pancreatic enzymes start digesting the pancreas itself. It may be caused by stones blocking the duct these secretions normally leave the pancreas by, but alcohol may be a cause. It can be a very serious illness. Pancreatic cancer is the 11th most common cancer in the UK (with 7,000 diagnosed annually).

Pancreatic cancer can easily be overlooked and survival rates are poor. Check out www.PancreaticCancerAction.org.

DIET AND OBESITY.

The basic constituents of any diet are protein, fats, carbohydrates, water, vitamins, minerals, salts, and indigestible roughage (fibre). All are chemicals whose structure and function are reasonably well understood.

In general terms, however, requirements can be described in terms of how many calories there are in the total intake of proteins, fats, and carbohydrates per day, and how these are distributed between the three classes of food. The other substances mentioned above are only required in trace or small amounts except for water; and roughage is only required to aid bowel movement stimulus.

The Process of Digestion.

During the process of digestion (described earlier) all proteins are split into their constituent amino acids; all carbohydrates are split into their constituent simple sugars and most fats are converted into fatty acids and glycerol. At this stage, and not until this stage, all these simpler building bricks derived from the three classes of food are absorbed into the body proper, and taken to the liver and other tissues. Here they are "metabolised." That is to say they are either burned as fuel for the various processes of the body; or they are built up again into proteins, fats, and carbohydrates of the special kinds the body needs. They will either be used to rebuild structures suffering ordinary wear and tear or they will be stored. Many of them will be converted into a different class from the one they came from when they entered the body. For example, excess carbohydrate is converted into fat; or if there is a shortage of carbohydrate, some will be made out of the protein amino-acids which would normally have been used for tissue growth and repair. Thus it is only a generalisation to say that dietary carbohydrates are fuel and proteins are for building bodily structure. The body can convert one into the other, and spoil the calculation.

Diet and Energy.

There is a great deal of confusion in people's minds about *energy*, and that is why the word *fuel* has been used above in connection with carbohydrates. The lay person uses energy as a term meaning something which allows us to leap about, running and jumping and skipping and dancing, and which keeps us from getting tired and run down. Thus, the food industry tells us, we need potatoes or breakfast cereals for these activities or for a hard day's work. This is a deliberate commercial confidence trick, and the scientist is largely to blame. He originally handed out the word energy to an eager food industry and an unsuspecting public, forgetting to explain that he meant it in the strictly scientific sense of fuel for bodily processes. It simply is not true that more potatoes, or more cornflakes will make you more active.

Indeed the reverse is the case, and after a certain point they will only be converted into fat and reduce your activity. The nutritionist measures energy as calories, which are units of heat. You must eat enough of these each day if you wish to remain alive, let alone active.

The Well-Balanced Diet.

All the three main classes of food provide calories, and in an ordinary well-balanced diet about 15% are provided by protein. Carbohydrates produce most of the remainder. Each gram of fat contains about twice the calories of a similar quantity of carbohydrate. We simply eat less fat than carbohydrate, because fat has a "high satiety value." It takes away the appetite for more. Proteins are mostly found in meat, fish, eggs, cheese, and milk. However, there is quite a lot of protein in many predominantly starchy foods like bread, and such grains as wheat, rice, and corn. Carbohydrates are mainly found in bread, potatoes, sugar, pastry, sweets, and so forth. That is one of the words which fortunately seems to be used by both scientists and laymen in much the same sense.

Some substances are absolutely essential to the body if life is to continue, even if they are only needed in trace amounts. These are substances which the body's own factories (like the liver) cannot make for themselves, even if they are provided with the correct ingredients.

Vitamins.

One group of such substances are the *vitamins*. Some of these are found in predominantly fatty foods (milk, butter, cheese and so on) and are known as the fat-soluble vitamins—Vitamins A, D, E and K; the others are water-soluble—the Vitamin B group and Vitamin C. All have now been chemically identified, are manufactured and can be bought over a pharmacist's counter. The myth has grown up that if a little is good for one then a lot more will be better and there are still many vitamin enthusiasts who consume vast quantities of such manufactured products in the belief that by doing so they will induce extra vitality and energy. Unless your diet is unbalanced in some way (a vegetarian diet may be grossly deficient in Vitamin B_{12}) you will not need extra vitamins.

Fortunately, most people buy food because they like it, not because it does them good; and provided they have normal dietary tastes they will usually get a perfectly adequate selection of the things we have spoken of as necessary for good health. The main danger in Britain is to have a surfeit and become overweight. In addition there are certain times of life when attention should be paid to what is necessary. For example babies and nursing mothers have special dietary needs. *See also* **Z42** for Vitamin A deficiency.

Popular Attitudes and Knowledge.

Recent surveys have revealed some interesting facts about people's attitude to food and their knowledge of it. For example, half the people asked knew that meat was a source of protein, a third mentioned eggs and a fifth cheese, fish, and milk. But practically no one knew there was protein in bread. Yet in England about a fifth of our daily protein intake comes from bread, and nearly a third from cereals as a whole. Fish is well known as a source of protein, but did you know that on average we only obtain 4% of our daily protein from fish—less than we get from potatoes (5%)? No one seems to know that potatoes are an important source of vitamin C, although fruit and vegetables are well-known sources. Calcium is recognised in milk, but most people forget its presence in cheese. Most people are very confused about iron. Why does everyone think it is mainly in green vegetables, when these are really such a poor source? For our daily requirement of iron we would each have to eat 1 kg. of spring greens or peas; or 2 kg. of sprouts! In fact meat provides one of our best sources; one-fifth of our daily needs is contained in bread.

Obesity.

Nowadays, obesity has become one of the greatest threats to global health even more so than hunger. Nearly 1·7 *billion* people on our planet are overweight. Being fat is dangerous to health and carries a high mortality. Ask any life insurance company how they view your chances if you are overweight and you will find they are as worried about it as if you had high blood pressure, or smoke heavily. It is a particularly important cause of heart disease. However, it is very important to know exactly what we mean by fatness.

The term *Body Mass Index* (*BMI*) is now a common measure of a person's weight relative to their height (above 25 is overweight, above 30 obese). The ideal ratio is between 18·5 and 25. The average *BMI* of women in the UK is higher than in many EU countries.

If you are overweight according to the tables below you need to slim, and the question is how? Answer: by will-power. There is no other satisfactory method than to decide to eat less. For the time being eat as much fruit, and green vegetables, as

DESIRABLE WEIGHTS FOR MEN AND WOMEN, AGES 25 AND OVER

Men Height (in shoes 2·5 cm heels)	**Weight in kilograms** (in indoor clothing)		
	Small frame	Medium frame	Large frame
157	51-54·5	53·5 59	57 64

183	63 67	65·5-72	69·5 78·5

you like, but no sugar, starch, sweets, cakes, pastry, or biscuits, and no eating between meals. And cut down on beer and other alcoholic drinks.

At the same time take more exercise. Walk to work. If you make a real and genuine effort for three months without success, you should ask your doctor for advice. Almost certainly you will have to admit you have not really tried. Good luck!

Nowadays, scientists blame genes not poor diet for childhood obesity—but exercise and careful diet remain vital. Remember, the number of under-18s on anti-obesity medicines has risen 15-fold since 1999. Obesity (particularly childhood obesity) is becoming a medical time-bomb and Britain is among the worst offenders.

NUTRITIONAL DISORDERS.

Nutritional Deficiency and Malnutrition.—Until quite recently a consideration of malnutrition would have merely led to an account of how too little food, or a deficiency of certain articles in the diet, produced deficiency diseases at the time of the restriction. For example lack of vitamins of various kinds gives rise to such diseases as rickets, scurvy, beri-beri, and pellagra; and an overall shortage of food to general starvation. These may be considered the immediate or concurrent effects of a poor diet. Modern nutritionists, however, are beginning to be concerned with two more kinds of nutritional disorders; and although the study of both kinds is in its infancy, both will be introduced in this account.

The first deals with the effects of comparatively small amounts of harmful constituents in our diet, introduced either voluntarily or involuntarily, and consumed for a long period of time; and the second with the lasting effects on our adult well-being of nutritional deficiencies in early life even though they have long since been corrected.

When viewed in this light, one or other of these three kinds of nutritional disorder may at this moment be affecting almost every individual in every part of the world, "privileged" or "underprivileged." Let us first define some terms.

Undernutrition, strictly speaking, means a state of affairs in which the quality of the diet is perfectly good. There is the correct balance of the various dietary constituents and all the necessary components are present: but there is simply too little of it. Many hundreds of millions of people throughout the underprivileged world are suffering and dying from this kind of undernutrition, and the simplicity of the problem must be appreciated: they simply need more food of the kind they are at present getting, and which can often be produced locally.

Malnutrition means an imbalance of the various constituents: a relative lack or excess of one or more of them. It usually leads to conditions which are, from the point of view of medical treatment, much more difficult to deal with. And so doctors often class them as "more serious."

The diseases of malnutrition range from the widespread protein deficiencies in other parts of the underprivileged world to *obesity* in our own better-off industrial countries, which is usually due to excess carbohydrate. Make no mistake: obesity (or being overweight) is a widespread disease of nutritional imbalance, and it kills.

Obesity is the commonest form of malnutrition in (for example) England and America today, and is a consequence of the sophistication of our diet in modern times. Recent figures for the UK show that the proportion of obese men rose from 13·2% in 1993 to 22·1% in 2005. The total is still rising. Over 22% of women are now classed as obese. If it is any comfort, obesity is a *global* problem. More people in the world are now fat than are undernourished. In the USA over 32% are now obese—the highest level in the world.

There are high authorities in the world of nutritional science who attribute all this overfed malnutrition to the consumption of refined sugar, or sucrose. They say it is not only the amount of refined sugar we put in our tea or on our breakfast cereals, but also the amount in sweet cakes, biscuits, drinks, chocolates and sweets, and so forth. For some people it adds up to a phenomenal quantity each day.

This school of thought says we are not so much suffering from a surfeit of carbohydrates or starches, but from this single sugar, sucrose. It is interesting to reflect on the recent banning of the artificial sweetener, cyclamate, by many governments. This substance, having been used extensively throughout the world as an apparently harmless non-fattening substitute for sugar, was suddenly banned in America because in very large doses (equivalent to the amount taken in hundreds of cups of coffee per day for a long time) it was found to produce cancer in rats. It has never been shown to do humans any harm, whereas the effects of sugar in producing an overweight population, thereby indirectly kill tens of thousands of British people each year. This is a fascinating example of the difficulties confronting our legislators in making balanced judgments when deciding to ban a foodstuff, a drug, or an artificial fertiliser.

Childhood Malnutrition.

Protein-Calorie Deficiency is much the most widespread form of malnutrition. In very large underprivileged areas of the world, the childhood population receives such an inadequate diet that children live continuously on the brink of nutritional disaster. It only requires a small extra restriction or stress to topple them over into one of the clinical conditions to be described. At this stage they cease to be merely hungry. They become nutritionally ill. Sometimes the force which produces the disaster is a community catastrophe like a famine, an earthquake, or a war. Sometimes it is a family catastrophe like the loss of a lactating mother or a parental delinquency. Parents abandon young children as often in Africa as anywhere else. Sometimes the clinical nutritional disease is unmasked by a common childhood illness like measles, or gastro-enteritis which the well-fed child would have overcome. The starved child reveals his malnutrition instead and frequently dies.

Kwashiorkor. Protein-Calorie Deficiency is a collection of different kinds of childhood malnutrition. Some are due predominantly to deficiency of protein and are collectively called kwashiorkor, a West African word meaning "red-haired boy" (*see below*). Others are mainly due to a severe deficiency of overall foodstuffs and are called *marasmus*. But in any real-life situation the severe *mal*nutrition of kwashiorkor exists side-by-side with all gradations between itself and the severe *under*nutrition of marasmus, so that many intermediate forms of "marasmic kwashiorkor" are described.

In kwashiorkor the child is typically listless, apathetic, whining, with a reddish discoloration of the hair, a peeling, scaly skin, and with much extra fluid in his tissues causing oedema. He is so listless as not even to be hungry. In marasmus the child is ravenously hungry. He is extremely thin and "starved" looking and is quite a different picture.

There is good reason to believe that even when protein-calorie deficiency is successfully treated, there will always be some lasting restriction of mental function, particularly if the malnutrition occurred as early as the first year of life. This is especially true in situations of appalling poverty in towns, where thousands of babies are not breastfed because their mothers are at work. Many of them die. Some of them are no heavier than their birth weight at one year of age. Breast feeding in an underprivileged community is an essential insurance for childhood health and survival.

Problems of Additives.

Two new avenues of nutritional inquiry were mentioned at the beginning of this section. The impact of very long continued intake of refined sugar over many years on our bodily health is an example of one of them. Scientists and others are also becoming alarmed at the effects of modern food additives when taken, even in small amounts, over a long period. These additives include colouring matter, decolorising chemicals, taste "enhancers," and so forth, which are present in everyone's diet in a "civilised community." We are as unable to avoid a constant dosage with them as if they had been added to our water supply. It is, however, difficult to strike a balanced attitude. It is one thing to suspect that these additives are harmful and quite another to prove it.

Naturally if any of them are shown to produce harm in animals given reasonable quantities they are invariably withdrawn. But in practice it is extremely difficult for animal experiments to mimic the conditions of human intake, especially as the human life span involves eating the substance concerned in small quantities for several decades.

New Views on Nutrition.

The other new topic in nutrition is more soundly based on animal experiment. It has been repeatedly found that if animals do not grow quickly enough at certain early periods of life they not only become small, but they remain smaller than they should be even when they are subsequently given as much as they like to eat. This is true of all animals and birds so far studied. At the moment it is difficult to know whether the same is true of humans and, if so, when is our period of vulnerability. There is some suggestion that the corresponding critical period in humans is during the last part of gestation in the uterus, and the first year or so of postnatal life. This new idea may turn out to be very important for world nutrition. Since there will not be enough food for all the children all the time, it may become important to concentrate our aid to underprivileged countries on certain sections of the population only.

It may be a good idea to see that pregnant mothers and small babies are specially fed. In this way we may be able to put off the periods of inevitable malnutrition until a time of life when it is recoverable. Such a plan would also go a long way to safeguarding the development of the brain which also occurs mostly at the same early time of life.

Even in Britain, we need to be aware of this problem. Vitamin deficiency can still occur, however, in elderly people living alone and not having a well-balanced diet. It also occurs for similar reasons in alcoholics, vagrants, *etc.*

Beri-beri is a group of diseases usually confined to the Far East where a diet of polished rice results in a poor intake of vitamin B_1 (thiamine). In one form there is oedema (*q.v.*); in another the peripheral nerves are affected leading to tingling and numbness. A similar condition is occasionally seen in alcoholics and diabetics. Treatment is with thiamine, and other vitamins too, since most sufferers are going short of more than one.

Pellagra is sometimes found among maize-eating populations and is due to a deficiency of several vitamins including niacin, another member of the B group of vitamins. There is dermatitis on exposed skin, and soreness of the mouth and tongue, with gastro-enteritis.

Scurvy is caused by vitamin C deficiency. It was at one time the scourge of sailors. In children bone growth is affected. At all ages there is bleeding into the skin (bruising), impaired wound healing, mental depression, and anaemia. Most fresh fruit and vegetables contain vitamin C and a diet containing these prevents the disease.

Vitamin A Deficiency is commonly found in children in some underprivileged countries. It causes permanent blindness, with thickening opacity and dryness of the whites of the eyes leading to ulceration of the eye. Beyond a certain stage, therefore, a child's sight cannot be saved. The only real hope is prevention, with an adequate diet.

Rickets, another disease of early childhood, is caused by deficiency of vitamin D. Bones are not properly calcified, and their softness leads to deformities of the legs and many other bones. Vitamin D can either be eaten in the diet or produced under the skin under the influence of sunlight. Therefore rickets commonly occurs when both the diet and the sunlight are inadequate. It was once very common in Victorian England but was almost wiped out after 1945 when margarine was fortified with Vitamin D. It is now making a return in the UK where Vitamin D deficiency levels are running high.

Doctors are reporting a sharp increase in rickets caused by children glued to TV, computers and video games and not going outdoors in the sunshine enough!

THE ENDOCRINE GLANDS.

Glands are structures or organs which manufacture secretions (except for *lymph glands* which are not glands at all and should be called *lymph nodes*). The secretions are of two main kinds. The first are passed down tubes, or ducts, or are secreted directly into the hollow organs, and act locally. Good examples are the salivary glands which make saliva and pass it down ducts into the mouth for digestion of its contents and lubrication. These are *exocrine glands*. The second kind have no ducts, and secrete their product straight into the blood stream. This secretion is called a *hormone* and it is carried to all parts of the body by the blood where it acts at a distance on some remote part. These are the *endocrine glands* or *ductless glands*, and a number of them will be discussed in this section.

The first hormone, or "chemical messenger," was discovered by the British physiologist Starling in 1904, but the effects of removing some of the endocrine glands were known centuries before.

Anterior Pituitary.—Many of the endocrine glands do not act as separate autonomous organs in spite of their great differences. They are organised into a well-disciplined band by a "master-gland" called the anterior pituitary. Somebody once called it the "conductor of the endocrine orchestra" and the phrase is still repeated *ad nauseam* in students' examination papers. The pituitary, consisting of its two parts, anterior and posterior, is not much bigger than a pea and it sits right in the middle of the skull, centrally beneath the brain and joined to the brain by a short stalk. This astonishing tiny nodule of tissue produces at least eight important hormones.

Growth Hormone, which is one of these is necessary for normal growth, and also has an influence on insulin. An excess causes *gigantism* and *acromegaly*, often coinciding with diabetes, and too little results in a form of dwarfism. Three others, known as *gonadotrophic hormones* regulate the cyclical and other activities of the reproductive organs and lactating breast. Another, *thyrotrophic hormone*, regulates thyroid activity.

Adrenocorticotrophic Hormone, or ACTH, as its name implies, looks after the activities of another important endocrine gland, the adrenal cortex. And there are several others.

Hypopituitarism, including *Simmonds' disease* and *Sheehan's disease*, results from destruction of the anterior pituitary. It is extremely rare, and is usually associated with difficult childbirth involving very severe bleeding. There are disturbances of all the functions mentioned above, particularly thyroid and adrenal failure (*q.v.*) with upset sexual function. Treatment is by replacing the lost hormones.

Hyperpituitarism, including *gigantism* and *acromegaly*, results from over-activity of the anterior pituitary, and is usually due to a tumour or overgrowth of the gland. In acromegaly the growth hormone is produced in excess over a long period of time in an adult. This results in overgrowth of all the organs except the brain, and it is characteristic to find enlarged extremities—feet, hands, and jaw. In gigantism the same has occurred during childhood and the result is a person who may be 2 m tall or more.

Posterior Pituitary. The posterior part of the gland is really a quite separate gland. The main hormone it produces is concerned with the excretion of urine by the kidney (antidiuretic hormone). Deficiency of the hormone results in *diabetes insipidus*, not to be confused with *diabetes mellitus* or "sugar diabetes." In diabetes insipidus, the patient produces enormous quantities of dilute urine. He consequently has a prodigious thirst and consumes astonishing quantities of fluids. Treatment is by replacing the hormone.

Thyroid. The thyroid gland in the neck secretes an iodine containing hormone called thyroxine. Excess of it causes *hyperthyroidism*, *thyrotoxicosis*, or *Graves' disease*. Lack of it produces *cretinism* in the growing child or *myxodoema* in the adult. Thyroxine is concerned with the metabolic rate of cells throughout the body, or the rate at which they work, as well as with the proper growth of developing tissues, especially the brain. Too much thyroxine as in thyrotoxicosis leads to over-activity, warm sweatiness in an over-excitable patient whose pulse is rapid and who is eating ravenously to try to replace the wasted energy. In spite of this the patient is very thin, and often has bulging eyes for a reason not yet understood. Treatment is by drugs which neutralise the thyroxine or by cutting out some of the gland. A *cretin* is a child usually born with insufficient thyroid. He or she is destined to grow poorly, and to mental subnormality of a permanent and distressing kind. If the condition is diagnosed soon after birth (and routine testing is now done) treatment with thyroxine can avert most of the trouble. In myxoedema, thyroxine is deficient in an adult. They become slow in all their bodily processes, the hair thins and their flesh is puffy with a dry, wrinkled skin. Treatment is by thyroid replacement. Rates of thyroid cancer have doubled over the last 25 years.

Goitre means enlargement of the thyroid gland. It may be accompanied by overactivity or underactivity, or with little functional change. One variety (Derbyshire neck) occurs in areas short of iodine in the soil and drinking water.

Adrenal Cortex. The adrenal or suprarenal glands sit, as the name implies, one on top of each kidney. There are two distinct parts: the cortex or outside which secretes steroid hormones, and the *adrenal medulla*, or core, which secretes adrenalin. There are many different steroid hormones in the adrenale cortical secretion, which look after such diverse matters as sodium and potassium balance, sexual function, reaction of the body to stress, and the regulation of sugar levels.

Addison's Disease results from adrenal cortical insufficiency, and is often due to destruction of the gland by tuberculosis. There is weariness, malaise, pigmentation of skin creases and mucous membranes. They are short of sodium and have excess potassium. Treatment is with cortisone or synthetic steroids to replace the missing hormone. and by extra salt by mouth for the lack of sodium.

Cushing's Disease is due to excessive adrenal cortical function, and sometimes also occurs in patients treated with steroids for other purposes. They have a striking redistribution of fat in the face, neck, and trunk, with stretch marks similar to those acquired by most women during pregnancy. The facial obesity makes them "moon-faced," and female patients may suffer masculinisation with deepening of the voice and hirsutism.

Testis. The male testes, as well as producing sperm are also endocrine glands producing steroid hormones known as *androgens*. They are mainly concerned with maintaining secondary sex characteristics. At the time of puberty the controlling secretions from the anterior pituitary begin to appear and androgens are produced. There is a whole range of rare disorders, resulting in everything from precocious puberty to delayed puberty. It should be borne in mind that the normal time of puberty can vary by several years from one boy to another. In passing, it should be noted that any lump or severe pain in a testicle requires urgent medical advice. These may be signs of cancer or twisting of the blood supply, respectively.

Testicular cancer, though rare, is the most common cancer in men aged 15–45. The risk of *testicular cancer* doubles with the use of cannabis. Any problem a man encounters in this area should be discussed urgently with a doctor. The good news is that nearly all men recover from testicular cancer. Men with an abnormally low sperm count are at greater risk.

Ovary. The human ovary has two functions: to produce ova, or eggs; and to produce two hormones, oestrogen and progesterone. These functions begin at puberty, one of whose features in the female is the onset of menstruation, or menarche. Just as in boys, the timing of normal puberty is very variable, but on the average, girls achieve puberty before boys. As social conditions improve, the age of menarche is getting younger generation by generation. All the secondary sex characteristics are under the control of the ovarian hormones which are released in response to the appropriate anterior pituitary hormones. The changes which occur in the womb and elsewhere in the intervals between menstrual periods and the periods themselves are controlled by a cyclical or rhythmic secretion, first of oestrogen and then of progesterone, by the ovary. This cycle is upset by pregnancy to allow the development of the embryo.

The cycle can also be upset by taking certain combinations of the two hormones by mouth. These can prevent the formation of ova, and are a popular form of contraception. In late middle age, the ovaries lose their function, the menstrual cycles cease to occur, and reproductive life is at an end. This is called the *menopause* or "change of life," and is sometimes accompanied for a time by distressing symptoms due to a temporary imbalance between oestrogen and progesterone. But many sexual functions continue long after the menopause.

Parathyroid. Four tiny parathyroid glands are buried behind the thyroid gland and are responsible for regulating the body calcium and phosphate. They are therefore particularly important for the building and maintenance of bones and teeth. Since a proper calcium level in the blood is necessary for muscle (including heart muscle) contraction, and for correct functioning of nerves, disorders of the parathyroids can give rise to muscular spasms as well as loss of bone calcium. The latter can result in fragility and fractures. Overactivity of the glands leads to too much calcium and the formation of stones.

Pineal. We end this section with a mystery gland. Like the pituitary it is small—about the size of a pea—and sits well back at the base of the brain. It was endowed in ancient times with metaphysical properties all of which remain speculative. In fish and lizards and certain lower vertebrates it is a kind of third eye, and receives light. In higher mammals, like ourselves, it is so far from any source of light that it could scarcely do so. It can be removed without harm. Indeed it normally becomes calcified and inactive about the time of puberty, and its position seen on X-rays of the skull can be a good guide to whether the brain is being pushed to one side by an abnormal mass.

THE URINARY SYSTEM.

Everyone knows what kidneys look like—in fact, the term "kidney-shaped" is used to describe other objects. Within the kidneys the blood-vessels carrying waste materials subdivide and finally end up in little coils or glomeruli through which waste products are filtered into the other system, the system of tubes which, beginning as tiny cups around the glomeruli, become larger and larger until they join the ureter passing out at the foot of the kidney, the hilum, a point at which both the veins and tubes enter and leave. The kidneys, of course, lie one on each side in the loins, so that if one puts one's hands on the hips and then slides them farther back they will cover the area over the left and right kidney. The ureters pass down on each side to the bladder, which is the storage tank of the products excreted by the kidneys, and lies in the mid-line down low in the abdomen; it is somewhat pear-shaped, and at its base in men there lies the *prostate gland*—a gland which apparently has few functions but can be a nuisance. Its only known function is that it adds something to the semen from the testes without which the semen would be sterile. Then, from the base of the bladder a single tube, the urethra, passes to the outside.

One can visualise the urinary system as a capital Y, in which the two upper limbs are the ureters, the place where they meet is the bladder, and the single limb at the foot is the urethra. Clearly, then, there may be diseases of the kidneys, of the ureters, of the bladder, of the prostate gland, or of the urethra.

Urine: Polyuria and Oliguria.

The amount of urine may be increased or diminished. It is *increased* in the following conditions: after drinking excess of fluids; after taking drugs (known as *diuretics*) which are given to increase the flow; in diabetes of both types—mellitus and insipidus; in some types of chronic kidney disease; and finally, in emotional states of excitement. It is *decreased* in the following conditions: acute nephritis; any disease in which fluid is being lost in other ways, such as diarrhoea or sweating in fevers; when the fluid intake is small; and when both ureters are blocked by stones.

Passing a great deal of urine is known as *polyuria*, passing very little as *oliguria*, passing frequent small amounts is simply called *frequency*. Normally, the urine is acid, but in infections of the bladder it may become alkaline owing to decomposition by bacteria. Abnormal substances, or normal substances in abnormal quantities, may occur in the urine and give the doctor an indication of what is wrong. In fact, urine analysis is a very important part of medical diagnosis. Thus urea is a normal component of urine which is increased in fevers, wasting diseases, or diabetes; the amount of urea is to some extent a measure of the degree of tissue breakdown. Uric acid is found in small quantities in normal urine, but the amount is increased in fevers and after an attack of gout (uric acid is important in the causation of gout).

Oxalates are not ordinarily found in urine, but, since they occur in such foods as rhubarb and strawberries, and some people are unable to deal with them, such individuals may develop problems.

Albumin and Sugar.

Two very important substances which ought not to be in normal urine are albumin and sugar. Albumin is a protein, and its presence in the urine indicates that the filters of the kidney are leaking—they are allowing protein to pass out which ought to remain in the body. Albumin is easily tested for, and its presence may indicate kidney disease or nephritis as it is usually called by doctors. On the other hand, small amounts of albumin occur in fevers and in nervous conditions—*functional albuminuria*. Sugar, too, should not be present, but its presence does not necessarily indicate diabetes; for small amounts may occur in nervous conditions or in some people after taking large quantities of carbohydrate.

Blood in the urine may give it an appearance which varies from bright red to a dark, smoky colour. It is found in many diseases: acute nephritis, stone, tumours, poisoning by certain drugs, infections such as bilharzia or malaria, papilloma (*i.e.*, non-malignant tumour of the bladder), after injury, in high blood-pressure, scurvy, and blood diseases. Sometimes it occurs for no known reason at all.

Nephritis. It will be remembered that streptococcal infection of the throat may cause in some people disease of the valves in the heart or endocarditis. In such cases, although the germ is found in the throat, it is not found in the heart or anywhere else in the body.

Acute Nephritis occurs in the same circumstances, with the sole difference that it is the kidneys not the heart which are affected.

The disease appears to be an allergic reaction to the toxins of the Streptococcus. The patient, often a child, has a sore throat (and even this may be absent or fail to be noticed) or sometimes the infection may arise in other sites: after scarlet fever, erysipelas, burns, and disease of the ear. A few days later there is headache, vomiting, pain in the loins, slight rise in temperature, and especially typical is *dropsy* or oedema. This begins in the face, first around the eyelids, and then affects the ankles; later it may become more general and affect the rest of the body. Blood and albumin are found in the urine, and the blood pressure is slightly raised. The outlook is usually good if the kidneys are rested by reducing the amount of protein taken in and also the amounts of salt and water. When this is done, the inflammation soon goes and no permanent harm results. In other cases, however, if treatment is inadequate or the condition severe, the symptoms may go, but the albumin found in the urine persists. This means that permanent damage has been done, and although there may be nothing else to show for many years, *chronic nephritis* develops.

Chronic Nephritis. With this disease, the blood pressure continues to rise, and since the filters of the kidneys no longer work efficiently, urea, the principal waste product of the body to be excreted in the urine, is retained in the blood and only small amounts escape from the system. Hence chronic nephritis sooner or later leads to heart failure or haemorrhage in the brain from the rising blood pressure, or to the form of poisoning known as *uraemia* which results from the retention of urea in the blood. Uraemia may come on suddenly or gradually, but ends in progressive coma, drowsiness, and unconsciousness. There may be convulsions and difficulty in breathing to complicate the picture.

Nephrosis is another type of nephritis which seems to have nothing at all to do with streptococcal infections, and the cause of which is completely unknown. Developing in early adult life, its onset is insidious, and the patient first shows signs of oedema in his white and puffy face and the swelling of his legs. (It should be said here that if you have swelling of the ankles or elsewhere, you would be foolish to jump to conclusions; for such swelling is common in many diseases—in heart disease, in allergic conditions, even hot weather.

When the urine is examined in a case of nephrosis it is found to be full of albumin and, as in chronic nephritis, the blood urea starts to rise. The end results of nephrosis are the same as those of chronic nephritis and depend upon the original damage.

The modern diuretics of the thiazide group help to control the oedema and, provided enough healthy tissue remains, remove both the fluid and the waste-products.

Artificial Kidneys or **Dialysers** as they are known, are widely used in patients' own homes, thus obviating in some cases long journeys to hospital twice a week for treatment. Dialysis is a relatively temporary measure; renal transplants now offer real hope to many sufferers although there are far more suitable recipients than potential donors. Currently 2,000 transplants a year come from deceased donors, 1,000 from living donors.

Pyelitis (**Pyelonephritis**), infection of the pelvis of the kidney, that is to say, of the part where the ureter leaves the kidney. Usually caused by Escherichia coli, which is normally present in the body, or by the Streptococcus. These germs may reach the ureter through the blood-stream or may pass upwards from the bladder. Obstruction anywhere in the urinary tract which causes the urine to stagnate is liable to cause pyelitis. Symptoms come on suddenly, with high fever, pain in the loin (the infection is usually on one side only, and is commoner in women), and pain in the abdomen. When urine is passed there is a burning sensation, and it is passed frequently and in small amounts, On examination, the urine is found to be highly acid and full of Escherichia coli or whatever the causative germ may be.

Pyelitis is fairly readily treated by the antibiotics or sulpha drugs. Plenty of fluids should be given and the urine made alkaline.

Cystitis means inflammation of the bladder, either acute or chronic, and its causes are much the same as in the case of pyelitis. There is pain over the lower abdomen, frequency, and sometimes slight fever. The treatment is as for pyelitis.

Urethritis is an inflammation of the urethra, with burning pain on passing water and frequency. The most serious cause (although it can usually be easily dealt with now) is gonorrhoea. But non-specific urethritis is common, especially in the newly wed and in this case various germs or none may bring about pain and frequency; there is often a large neurotic element.

Urethritis should be regarded as probably due to gonorrhoea when there is a thick, creamy discharge from the penis or discharge in women following sexual intercourse with an infected person.

Kidney Stones *or* **Renal Calculi** sometimes form, and, as in the case of gall-stones, what causes them is not certain. They may be caused by disorders of metabolism—that is, in the inability of the body to deal with calcium, proteins, uric acid, and other products; or by vitamin deficiency, obstruction in the urinary tract, and urinary infections. But when a stone or stones are formed various events may occur: thus it may remain in the kidney and cause no symptoms; or it may cause repeated attacks of pain, infection, and blood in the urine (haematuria); or it may completely block the passage of urine from the kidney to such a degree that it degenerates and becomes useless; or, lastly, it may pass into the ureter, and when this occurs very severe pain, known as *renal colic*, will occur. A stone passing down the ureter into the bladder may become stuck in the urethra, although this is uncommon, since a stone small enough to get down the ureters is likely to be capable of manoeuvring through the rest of the tract. In fact, about 80–90 per cent. of stones are passed spontaneously.

Stones not passed spontaneously may have to be removed by operation, but whether this is undertaken or not depends on various factors, such as the health of the patient, the amount of trouble caused by the stone, and the health of the other kidney—for it is dangerous to operate on one kidney unless one is sure that the other is functioning efficiently. Lithotripters are also used to fragment stones without needing invasive surgery. Emergency hospital admissions for kidney stones have doubled in the last decade.

Hydronephrosis. If a stone blocks the passage of urine on one side for any length of time *hydronephrosis* may result, in which the part where the ureter enters the kidney swells with the retained urine. Ultimately much of the kidney may be destroyed by the back-pressure. The same effect may be produced by kinking of the ureter or anything else which causes obstruction. Sometimes children are born with hydronephrosis, and when the dilation is due to kinking of the tube the condition may be intermittent, with attacks of renal colic during which only small amounts of urine are passed; this is followed with relief and the passage of large quantities.

Cancer of the Kidney. The kidney may also be the site of tumours and cysts which produce pain in the loins, sometimes a lump over the kidney which can be felt, and blood in the urine. Cases of kidney cancer have risen by a third in the last 15 years.

Cancer of the Bladder is a serious condition in which the bladder may have to be removed, so the urinary flow has then to be directed elsewhere. Either the ureters are brought out on to the skin surface, a procedure known as *cutaneous ureterostomy*, or they are implanted in the large bowel, so that the urine flows out with the faeces. This is described as *uretero-colostomy*. Men infected with gonorrhoea are twice as likely to develop cancer of the bladder.

There may also be benign tumours of the bladder or *papillomas*, which are soft and bleed easily; a great deal of blood is passed, but there is usually little or no pain. In this, and similar, diseases of the bladder examination of the inside of the organ is carried out by means of a cystoscope, a thin tube which is passed up the urethra with fibre-optic light guides which enable the surgeon to see what is going on. Instruments may also be passed through the tube, and simple papillomas can be cauterised. Similar instruments are used to examine the stomach (gastroscope) and the bronchial tubes (bronchoscope).

When some obstruction in the outlet of the bladder or in the urethra occurs the bladder, of course, fills with urine, which cannot be passed, and very painful dilation occurs. In this case an attempt may be made to pass a catheter, a thin rubber tube, into the bladder to relieve the tension, or if this fails a *suprapubic cystotomy* is performed -an incision is made in the abdomen over the bladder and a tube inserted into it, through which the urine escapes.

This is ordinarily a temporary expedient, and when the patient's health has improved an attempt will be made to remove the cause of obstruction.

Prostate Gland. The common cause of such obstruction is *enlargement of the prostate gland* at the base of the bladder, which surrounds this area and the beginning of the ureter. About 40% of men over sixty have some degree of obstruction due to this cause, and *c.* 20% of these require an operation. More information is available at www.ProstateUK.org

The gland is the size of a walnut, and, as we have seen, its function is to supply part of the fluid which makes up the semen, the male sex secretion. Enlargement of the prostate may be benign or malignant, and, although nobody knows just why, such benign enlargement tends to occur in most men in later life. There may be no symptoms, but characteristically there is frequency during the day and the need to get up at night to pass water. The flow of urine being impeded by constriction of the urethra, the passage is less forceful than normal, and there is a tendency for dribbling to occur. If the obstruction is severe and not relieved the backpressure may be transmitted to the ureters and kidneys, resulting finally in kidney failure and uraemia. The prostate, except in cases of very mild enlargement, has to be removed either through the abdomen or through the perineum (the part of the body lying between the sex organs and the anus). Sometimes, in less serious cases, it is possible without an incision to cut away the obstructing part by an electrocautery inserted, as is a cystoscope, through the urethra.

Prostatectomy was once a serious operation, all the more so because the patient was usually elderly and not in good condition, but new techniques and the use of antibiotics have transformed the outlook.

Cancer of the Prostate is a potentially serious disease, but if diagnosed early and is localised, may be cured by surgery or radiotherapy. If the disease spreads, or has spread at the time of diagnosis, it can often be controlled. It can often be diagnosed early by a PSA blood test (all men should consult their GP from time to time over this). It is the second commonest male cancer in the UK (killing 11,000 men a year). Each year around 42,000 men are diagnosed with this cancer. African-Caribbean men are three times more likely to develop prostate cancer. Asian males are less likely. A new genetic test for the disease is now available. And new blood tests are being developed. Readers may wish to refer to www.prostate-cancer.org.

THE NERVOUS SYSTEM.

The nervous system consists of the central nervous system and the peripheral nervous system. The brain and spinal cord make up the former. The latter consists of the nerve fibres by which the central nervous system is connected to all parts of the body. Human beings have a more complicated brain than any other animal species, but it is only its complexity which makes it different from the brains of other mammals like rats and pigs and cows. We do not have the largest brains, since whales, for example, have much larger ones. Ours is not even the largest for the size of the body.

Before describing some of the diseases of the nervous system it will be helpful to say a little about how it is made and how it works. Each human brain probably contains about ten thousand million (10,000,000,000) nerve cells and perhaps four or five times this number of supporting "glial" cells. Each nerve cell has many long thin branching projections, called dendrites, rather like the branches of a tree, leading to many thousands of "twigs" for each single nerve cell.

At the end of each "twig" there is a special structure called a *synapse* by which contact is made with other nerve cells. It is through these connections that very large numbers of nerve cells give information (or send impulses) to each other so that they can be co-ordinated. As well as these dendritic branches, each nerve cell gives off one large trunk called the *axon*, down which final messages are sent as the result of all the information it receives from its dendrites. Some axons are many feet long. Some end in another synapse, by which the outgoing message is passed to yet another nerve cell. Some axons, those of the peripheral nerves, end directly on organs like muscles or glands, instructing them and making them work.

Transmission of Messages. Messages are passed along dendrites and axons as electrical impulses. These are generated in the nerve cell "body." They are modified according to information received from other nerve cells and propagated down the axon. It is this superficial resemblance to a series of electrical cables which has given rise to comparisons of the brain with a telephone system or a computer, and the comparison is not a bad one. However, the brain generates its own electric power from the fuel brought in its own blood supply; and no spare parts or spare cables are available if the originals should get damaged, except in peripheral nerves. Furthermore the contact of one nerve cell with another through a synapse is not an electrical contact, and neither is the contact between a nerve and the muscle or other organ it is controlling. In both cases the connection is chemical. Thus when an electrical impulse arrives at the end of the nerve fibre, a chemical is released into the gap between it and the next nerve or organ, and it is this chemical which carries the stimulus forward. There is also an arrangement to neutralise the chemical transmitter when the impulse has been transmitted. So the resemblance to a telephone exchange or computer can sometimes be misleading.

Myelin Sheaths.

Many of the nerve axons which transmit electrical impulses are clothed in fatty *myelin sheaths*, a little like the plastic insulation around an electric wire. Here again the resemblance is only partial, since the myelin sheaths are interrupted at regular intervals and these gaps in the insulation play an important role in transmitting the impulse. One of the important functions of the non-nervous *glial* cells of the brain is to manufacture and maintain the myelin sheaths.

The Functions of the Brain.

Many of the functions of the brain are little known, and even the ones we know about are very poorly understood. It is the organ of higher mental function, of the mind and intellect, but much remains to be done on linking the different functions of the brain with the structures found within it. The brain is known to control all bodily functions by means of *motor* and other nerves which carry impulses from the brain outwards to all parts of the body. Sometimes these are under our voluntary control; mostly they are involuntary, reflex or automatic. Reflex actions are the result of impulses passed inwards from the body towards the brain by means of sensory nerves. Information arriving in the brain about the various sensations like heat, pain, touch, position, the need for saliva or gastric juice or even the thought or smell of food, are acted on in the various "centres" in the brain. These send out instructions down the "motor" or "secretary" nerves which instruct the muscles or glands to take appropriate action. Thus a *reflex* has a "sensory ending" which appreciates some sort of sensation. This is converted into an electrical impulse which is sent towards the brain or spinal cord along a sensory or "afferent" nerve. The impulse arrives at a "centre" in the central nervous system which co-ordinates all the relevant information and issues instructions. These travel as impulses outwards, along "efferent" nerves towards "effector" organs like muscles or glands, and an appropriate action occurs automatically.

The pathway from sensory ending to effector organ is called a *reflex arc*. Many reflex activities are partly under voluntary control, although mainly automatic. If you touch something hot you will automatically withdraw your hand. But if it is a hot china cup which has cost you a lot of money, you are capable of overriding the tendency to drop it, at least for a time. Breathing is automatic, but it can also be controlled, again at least for a time.

Clearly the brain is a very delicately organised piece of machinery, and its cells are extremely specialised for their job. Achieving this kind of specialised perfection brings many difficulties, however, and the brain cells have become highly dependent on the proper functioning of the other body systems, especially the blood circulation, the respiratory system, and the systems regulating the detailed nutrient composition of the blood. Failure of these systems, even for a very short time, can damage the nerve cells. Nearly all death is produced this way, by an ultimate interference with nerve cell function.

Recently, scientists have shown that the brains of men and women are wired completely differently.

Vulnerability of the Brain.

We have already mentioned that the brain and spinal cord are unable to repair or replace any components which get damaged. The vulnerability of the brain is even more obvious when it is realised how easily damage and destruction can occur. For example, unless a rich supply of oxygen and glucose is continuously arriving in the blood stream, brain cells will cease to function in a few seconds and will die in a few minutes, and they can never be replaced. This is in marked contrast to other tissues of the body. The leg, for example, may carry on for over half an hour without any blood at all because the muscle and other cells can find other ways of surviving. Thus the brain can be permanently damaged if the blood contains insufficient oxygen (through asphyxia), insufficient glucose, or if the blood supply is blocked or if the blood pressure falls.

All these are likely to happen to any of us at any time, and so there are elaborate mechanisms trying to prevent them occurring. Much of the subject of physiology is concerned with the mechanisms designed to protect the brain, and most of us ultimately die because they eventually fail. One of the clever features of the body design is that all the mechanisms which protect the brain from a supply failure are controlled by the brain itself. Thus the brain has itself been made to control the heart beat and the breathing and the many other systems which are needed for its own survival.

Diagnostic Techniques in Neurology. The doctor has many ways of testing the nervous system, most of which test its various functions as outlined in the introduction. Thus tests of sensation, muscular movement and reflexes of all kinds as well as the special functions of taste, smell, vision, hearing, speech and intellect play a part.

A great deal can be learned about the brain by *arteriography*. In this test a radio-opaque substance is put into the arteries supplying the brain, and an X-ray picture taken immediately afterwards shows up all the blood vessels. *Myelography* is an X-ray of the spinal cord after a radio-opaque substance has been injected into the space between the spinal cord and the bony vertebral canal housing it.

Computerised tomography (CT) scanning and Magnetic Resonance Imaging (MRI) have now made "invasive" diagnostic tests less necessary.

In another development, *radioactive isotopes* can be put into the blood stream and carried into the brain where they can be detected from outside the skull by counters. *Electroencephalography* measures the electrical waves generated by the brain by placing electrodes on the scalp. *Electromyography* does the same for muscles.

Consciousness and Unconsciousness (Coma). Everyone knows what consciousness is until he tries to define it. Full consciousness is generally taken to imply not only wakefulness but the total complement of human mental faculties. In clinical medicine, however, something less than this is usually meant. For example a demented person, or one whose memory is lost (*amnesia*), or one whose powers of speech are lost (*aphasia*) may still be "conscious."

There is really a continuous gradation between full consciousness and coma, passing through drowsiness and even "stupor" in which condition a patient can be aroused from coma but sinks back into it when left alone.

Many different things can cause coma ranging from swelling of the brain, compressing it in its rigid box of bone, to disorders in other body systems resulting in a failure to provide for the brain's needs. Examples of the first are bleeding within the brain or *brain tumours*, both of which occupy space and can only do so by producing compression. In the second category are asphyxia preventing oxygen from reaching the brain, lack of glucose in the blood, circulatory failure in which there is insufficient blood, or insufficient blood pressure. Fainting is a comparatively minor example.

Sleep and Insomnia. The real reason for sleep is to produce myelin, to replenish the brain cells. Sleep is quite different from coma or even stupor, since as much oxygen and glucose is necessary asleep as awake. Insomnia is experienced by everyone at some time, and for some reason can be very distressing if it persists. There are three forms: failing to get to sleep, intermittent wakefulness, and awaking early. Nearly all insomniacs sleep more than they think. They should eat light evening meals and avoid stimulants like tea and coffee after mid-day. Elderly people should realise they need less sleep. Being cold or having a full bladder can be a cause. Or simply not being tired. Sedative drugs are a last resort, but they can be useful in "breaking the habit" of wakefulness. Obviously there may be psychological factors such as anxiety and excitement.

Narcolepsy, a true inability to keep awake is rare. The name was coined by Jean Baptiste Édouard Gélineau in 1880.

Headache. We must distinguish between the very common varieties of comparatively trivial significance and the rare ones due to serious causes. Some headaches are due to continuous tightness in muscles of the scalp, and are often "nervous" or psychological in origin. Others result from nose blockage and congestion, sinus problems, eye strain, toothache, *etc*. Migraine is a special kind and will be described below. Very occasionally indeed headache is due to serious disease like brain tumour. Most headache results from "living it up" or being "run down," or both.

The headache of alcoholic hangover is probably due to dehydration. It can often be avoided by consuming a great quantity of water (a half litre or so, before going to bed), but few people are prepared to do this in the circumstances. Be careful when using aspirin, which is a useful remedy for headache, since it is very dangerous for people with stomach complaints. Occasionally aspirin makes the stomach bleed, and this can be so severe as to kill. Paracetamol is much safer.

Migraine. This is a very special variety of "sick headache" and requires special treatment under medical supervision. It has many different forms, but usually there is a definite sequence of events. An attack often starts with some alteration of vision. The patient has shimmering blind spots or other visual disorders. This is followed by a localised severe headache. The whole thing is caused by a poorly understood disorder of the blood vessels. There are special drugs, which are effective, especially if used when the first signs of an attack appear. Handheld devices to "zap" the brain with magnetic pulses have been introduced. A gene linked to migraine was identified in 2011. Migraine affects more women (18%) than men (8%). It has been linked to brain lesions.

Although there is a direct physical cause for an attack, it is also certain that some of the trouble is psychological tenseness. People with migraine are often rather anxious, striving and perfectionist people. Also it has been noticed that attacks are much less frequent when the necessary pills are being carried available for use. However, as with all other conditions which are partly "psychological" in origin they are none the less distressing for the patient. It simply means that the treatment is also partly psychological. Readers may wish to go to www.migrainetrust.org for further information.

Menière's Disease is one of the conditions in which the organ of balance in the middle ear is affected, giving rise to *vertigo*, a form of giddiness. It usually begins in middle life in the same sort of person who sometimes has migraine. There is buzzing in the ears and some intermittent loss of hearing as well as vertigo. During an attack the patient may be unable to walk because of his loss of balance, and nausea and vomiting are common. Treatment is by special drugs, and occasionally an operation on the ear is necessary.

Epilepsy is a symptom, not a disease, which is common at all ages but especially in children. It is the most common brain disorder in every country. In the UK alone there are 450,000 sufferers. Epilepsy Research UK has a helpful website (www.eruk.uk).

Many varieties of attack occur often in the same patient, the commonest and best known being the *grand mal* or major seizure. In this the patient falls down unconscious and rigid and the jaw is clenched, so that there is danger of the tongue being bitten. This so-called *tonic phase* is followed, within a minute or so, by a *clonic phase* in which the limbs contract rhythmically. The attack ends with the patient going limp and gradually recovering consciousness, a process which may take up to an hour. Occasionally the patient has a brief warning, most often an indescribable feeling in the stomach.

Dravet Syndrome is a severe form of epilepsy.

Minor Seizures. There are two common forms of minor seizure, one occurring mainly in children and the other more often in adults. The common minor attacks in children are often called *petit mal* or *absence*, which well describes the instantaneous and brief loss of consciousness often unaccompanied by any change in posture. Recovery is equally instantaneous. On the other hand, in the other forms of epilepsy which arise from various parts of the brain, but especially from the lobe under the temporal region, there is often a warning similar to that which may precede a major seizure. In these cases the patient shows only confusion, no definite loss of posture, but automatic activity such as fumbling with buttons, muttering, and grimacing. After these attacks there may be a period of confusion in which the patient may wander away and even be violent.

Convulsions. Many people have had one or two fits in their lives, maybe at times of physical or psychological stress. "Fever" or "Febrile" convulsions (often called teething fits in the past) are extremely common in young children and are often thought of as something different from epilepsy since the attacks rarely continue in later years. This form of epilepsy and some cases of *petit mal* are the only forms in which hereditary factors are important in the causation, and these are the least serious forms of epilepsy. They are very rarely associated with serious physical or psychological disturbances. Most other forms of epilepsy are due to a scar or other area of brain damage. It is a proportion of these cases which develop the psychological disturbances that are occasionally very serious.

Not every patient who has had one or two fits need necessarily take regular anticonvulsant drugs; that is drugs which damp down the abnormal excessive activity of the brain that leads to the attacks. Many new drugs can now be used.

Patients, however, often find it difficult to get work because of the reluctance of employers to take on someone who may be more prone to accidents and whose fits may distress other workers. Obviously there are some jobs which epilepsy sufferers should not do because of the danger involved (from for example, moving machinery), and they should not drive a car. A few cases are so severe that work is almost impossible, but employers have a duty whenever possible to employ these people whose mental health may suffer greatly if they are made to feel outcasts and who ordinarily are as efficient, or even more so, as the next person.

Congenital Malformations. The proper shape of the brain and spinal cord is achieved quite early in development by about the thirteenth week after conception. During this time very slight changes in the foetal environment can produce disastrous malformations. The drug thalidomide, for example, operated on other body systems while they were passing through this phase of construction. Some viruses can do the same thing. Most malformations are without known cause, but it is certain that something went wrong at this very early stage, and it only needs a very minor interference with the normal process to do the permanent damage. At about this time the bones of the spine are beginning to enclose, or form a roof over the developing spinal cord. Sometimes they fail to complete the process, resulting in *spina bifida*. If the coverings of the cord protrude through the defect, this is a *meningocoele*, and if the cord itself protrudes it is a *meningomyelocoele*. The whole protrusion may be covered with skin, but if it is not, the cord soon becomes infected. The effect on the patient is variable, according to the amount of damage to the nerve fibres in the cord, and there are varying degrees of paralysis and loss of sensation below the area involved and loss of bowel and bladder control.

Much help can often be obtained from surgical repair, but many cases remain in a distressing condition always, and the only really useful attack on the problem is research to find the cause and prevent it happening. The same is true of the *malformations of the brain*. In one of these, hydrocephaly, the narrow channel is blocked which transmits the cerebrospinal fluid from the chambers within the brain where it is secreted to the outer coverings to be taken back into the blood stream. Blockage of the channel (or aqueduct) results in distension of the brain by fluid, enlargement of the head, and mental retardation. Sometimes a by-pass valve can be inserted to restore normal fluid circulation.

Cerebral Palsy is a physically disabling condition of impaired muscle co-ordination caused before, during or shortly after birth by damage to or maldevelopment in the portion of the brain which controls movement. There are 3 main types: *spasticity*, *athetosis*, and *ataxia* depending on what area of the brain has been affected. Inherited defects do not play a large part in cerebral palsy. The general incidence of the disorder is thought to be 2·5 per 1,000 births. For further information and advice contact: SCOPE, 12 Park Crescent, London W1N 4EQ.

Motor Neurone Disease. This is a group of related diseases usually occurring in people over 40, in whom the parts of the brain and spinal cord which look after muscular movement degenerate. The group includes *amyotrophic lateral sclerosis, progressive muscular atrophy, progressive bulbar palsy*, and *primary lateral sclerosis*.

The results are paralysis or weakness with wasting of the muscles of the body, including those concerned with arms, legs, breathing, speaking, *etc*. At present, it is a fatal, progressive disease. Around half of those diagnosed die within two years. The Motor Neurone Disease Association provides help and advice. *See* www.mndassociation.org

Parkinson's Disease, formerly known as the shaking palsy, derives its present name from the London physician James Parkinson (1755–1824). It is one of the commonest illnesses to affect the human brain with more than one in 500 of the population as a whole (though one in 100 of those above 60 years of age) suffering from it. The average age of onset is about 55 though one in seven contract it before they reach 50. It has three classical features: shaking (or tremor), muscular rigidity and poverty of movement. A stooping, shuffling gait and a mask-like loss of facial expression are common. It is a progressive disease affecting patients in variable degrees of severity and different degrees of progression. A good deal can now be done to help these patients with drugs and since the condition results from a malfunctioning of brain cells which produce a chemical 'messenger' known as dopamine replacement of this substance by the drug L-Dopa (often accompanied by an additive in a combined preparation) is often the first line of treatment. Occasionally younger patients have benefited from surgical destruction of small areas of diseased brain.

In rare cases the disease is hereditary, but normally the cause is unknown (although a gene responsible for some cases of Parkinson's has been found). A link with depression has also been found. Sometimes people with Parkinson's may also develop dementia–a doubly cruel blow. Scientists are now considering the possibility of using cloned embryonic stem cells.

It is important to remember that many old people have some tremor of the head or hands called *senile tremor* and this is *not* Parkinson's Disease. It is merely one of the features of achieving advanced seniority as a citizen. The Parkinson's Disease Society sponsors medical research and patient welfare.

Chorea. This is a group of diseases in which there is involuntary muscle movement, weakness, and emotional instability. There will be clumsiness, awkward gait, twitching of limbs, face, hands, trunk, or tongue. They include *acute chorea* or *St. Vitus' dance* occurring in children from 5 to 15, *hereditary or Huntington's chorea* occurring in a well-defined genetic pattern and beginning later, between 35 and 50. *Tics* or habit spasms are not part of these diseases but are often of psychological origin. They are usually eye blinking or head shaking.

Stroke Illness *or* **Cerebrovascular Diseases.** Strokes are due to diseases of the brain's blood vessels which either burst or get blocked. The same blood vessel disorders cause heart attacks by blocking the coronary arteries supplying the heart. Strokes and heart attacks together kill more people than any other single cause including cancer. They account for one death in every five. Perhaps less is known of the cause of this disease than is known about cancer, and much more research is needed to find out if it is to be prevented.

Massive advances in the care and treatment of stroke victims have been made. Treatments such as *thrombolysis* restores the flow of blood to the brain. Improvements in *rehabilitation* have taken giant strides towards limiting long-term effects.

Infarction. If any artery supplying blood to any part of the brain is blocked, the territory supplied will die; and the bodily functions for which that part of the brain is responsible will cease. The process is called *infarction* of the brain, the dead area being an *infarct*. The blockage is usually due to thrombosis of the blood within a vessel, a *thrombus* being a rather complicated clot with a structure of its own. The underlying cause is the arterial disease, *atheroma*, together with stagnation of the circulation. About one blockage in ten is due to a small piece of a much larger thrombus in the heart chambers being flung into the blood stream and impacting in the distant vessel in the brain. This is *cerebral embolism*.

If the area of dead or infarcted brain is not too large the patient will recover from his unconsciousness, but will be left with permanent loss of function (paralysis, *etc.*) related to that part of the brain.

When a blood vessel supplying the brain bursts, this causes *cerebral haemorrhage* or apoplexy. The vessel may be on the surface (*subarachnoid haemorrhage*) or in the depths of the tissue (*intracerebral haemorrhage*). Strokes tend to occur in older people, because the associated arterial disease is a product of age and high blood pressure.

Occasionally a subarachnoid haemorrhage occurs in a younger person with an unsuspected malformation of the arteries of the base of the brain known as a *berry aneurysm*. This is a small berry-sized blown-out balloon due to a defect in the wall of the vessel. Berry aneurysms can often be treated surgically. Intracerebral haemorrhage carries a very poor outlook, however, since much brain tissue is often destroyed by the escaping blood, especially the deep tissues responsible for the vital functions.

Haemorrhage within the brain cavity can also be caused by injury.

Inflammatory Diseases of the Nervous System. The membranes covering the brain are called the meninges. Inflammation of these, nearly always by blood-borne infection or infection following injury, is called *meningitis* (*see* **Z13(2)**). Cerebrospinal or spotted fever was only one variety caused by a germ called "meningococcus."

Almost any other germ may cause meningitis, and when the germ is susceptible to one of the antibiotics it is usually treatable. It will usually be necessary to identify the germ by taking a sample of cerebrospinal fluid from a convenient space around the spinal cord in the lower back. When the disease is caused by the tubercle bacillus (*tuberculous meningitis*) the problem is more difficult because the patient is often not so obviously ill until the later, less treatable stages.

Cerebral Abscess, or abscess of the brain is very serious because it occupies space in the closed box of the skull and compresses the brain, as well as being a destructive process. It may arise due to an infected piece of tissue or pus being carried to the brain in the blood stream from a distant site in the lungs or heart.

Encephalitis. When the brain or cord tissue is itself inflamed it is called *encephalitis* (brain) or *myelitis* (cord) or *encephalo-myelitis* (both).

Herpes Zoster (**Shingles**) is a common viral infection of the nervous system which affects sensory nerve roots where they enter the spinal cord. The initial symptoms are of pain in the area supplied by the affected nerves—commonly one side of the trunk, the buttock or the face—followed by the appearance of blisters. Treatment nowadays is usually with a course of the drug Zovirax. Soothing lotions may be applied to the blisters and analgesics given for the pain. The disease is fairly short-lived, but neuralgia may persist for weeks after the blisters have healed.

Shingles is interesting in that it is not a *primary* viral infection, but the result of reactivation of the varicella-zoster virus (so called because it causes *either* chicken pox or shingles) which has lain dormant in nerve root cells, probably since childhood. Primary infection with the virus at whatever age causes chicken pox, not shingles; if an adult who has never had chicken pox or shingles comes into contact with a child with chicken pox or an adult with shingles, he is likely to contract the former but not the latter.

Shingles is infectious from the time the blisters appear until they have crusted over and healed. However, it is not as infectious as chicken pox. The NHS offers shingles vaccine for the over-70s.

Multiple Sclerosis (**MS**) is the most important of the *demyelinating diseases* in which the myelin or "fatty" sheaths which insulate nerve fibres appear to disintegrate. This occurs patchily and seemingly randomly throughout the central nervous system (*i.e.* the brain and spinal cord) and results in interference with the passage of impulses through the affected nerves. Changes in sensation, balance or muscular co-ordination occur at varying intervals of time and spaced out over months or years in such a way as to appear unconnected. There is at present no reliable, objective diagnostic test for multiple sclerosis and diagnosis has to be made from the history of such episodic symptoms.

The cause is unknown, but one theory is that MS is the result of a recrudescence of a dormant viral infection which may be picked up during the teenage years.

Others hold it to be an auto-immune disease. It is commonly held that once diagnosis of MS is made it means a sentence of years of increasingly severe disablement which will progress relentlessly and inexorably. That may be the case, but in fact such a gloomy picture is very uncommon. New treatments (such as injecting patients with their own bone marrow stem cells) continue to give hope for sufferers. A new drug, alemtuzumab, offers promise of reversing the disease in its early stages. Two new treatments, using fingolimod and cladribine, are the first MS treatments in tablet form. Benztropine, a drug used to treat Parkinson's disease, has been found to repair nerve fibres damaged by MS. Recent studies suggest vitamin D plays a major role as well as lack of exposure to strong sunlight. Stem cell treatment may offer exciting future possibilities.

Much research has gone into the natural history of MS and it is clear that there are various distinct patterns of the disease. These cover a wide range of symptom patterns from that characterised by a sudden onset of symptoms with relatively few relapses after the first year, to that manifested by sudden onset followed by unremitting relapses causing progressively greater degrees of physical impairment which may indeed lead to much distressing disability and relatively early death. But between these two extremes, of which the first is far the commonest form for the disease to take and the latter relatively infrequent, there lies a whole range of disease patterns and prediction is difficult.

In 2011 researchers found what they called the "missing link" in treating MS - a new molecule that could lead to drugs to repair damage caused by MS. Also, it appears a 'salt overload' in the brain may be a major factor. There is also evidence linking MS to low levels of Vitamin D. More than 100,000 people in the UK suffer from MS and it is the most common neurological condition affecting young adults.

The Multiple Sclerosis Society exists to sponsor research, to care for patients and to give advice and support to friends and relatives. The web address is www.mssociety.org.uk.

Brain Tumours. The brain is no exception to the rule that any cell in any tissue of the body can suddenly begin to disobey the body's rules regarding its growth and multiplication. A largely unknown mechanism governs how many cells of a certain type there ought to be and calls a halt to cell multiplication when this number is reached. Every now and then one of them turns a blind eye and goes on dividing, and the result is a tumour, or lump, of anarchic cells which obey no rules. Tumours are commonest in cells which normally go on dividing throughout life, in order to replace those lost by wear and tear. Examples are the cells lining the air passages in the lung, or the alimentary tract in the stomach or large bowel. Fortunately for the brain there is little cell division once it has grown. Nerve cells cannot divide at all in adult life, and the supporting glial cells only do so in response to injury.

Primary brain tumours are therefore much less common than those elsewhere. Also many brain tumours like many of those elsewhere, are benign or "innocent" tumours. They are not cancerous, and need only be removed for the patient to be completely cured. The brain, however, is at two major disadvantages compared with other tissues when it comes to tumours. One is that all tumours as they grow take up space, and space in the skull is already fully occupied. Thus even an innocent tumour can compress the brain within its rigid box of bone and become most dangerous until it is removed. The second disadvantage is due to the very large blood supply of the brain. Cancer in other parts of the body spreads partly by sending small pieces of itself to other tissues by way of the blood stream, and those tissues like liver, lung, kidney, and brain which have a big blood supply naturally receive more than their share of other tissues' tumour. These secondary deposits, or *metastases*, cause compression and other trouble in the brain much more frequently than the brain's own primary tumours. Indeed convulsions or other signs of brain disorder may be the first indication that there is a primary tumour in the lung or breast or elsewhere.

Diseases of Peripheral Nerves. Compared with the nerves of the central nervous system (brain and spinal cord), the peripheral nerves are comparatively rarely affected by disease. They have some similarities of structure with central nerve fibres in that their fibres are often covered with myelin sheaths and are arranged in bundles. A special feature, however, is that they are enclosed by connective tissue sheaths and it is probably these which allow a peripheral nerve to grow again, or regenerate, after it has been cut or damaged. Central nerve fibres are unable to do this. After *injury of a peripheral nerve* the part away from the centre is cut off from its parent cell body and it dies. All function, whether motor or sensory, is lost. But in the course of many months the central surviving part grows into the connective tissue sheaths which act like tubes to guide the new nerve to its destination. Provided the cut ends are close enough together and correctly aligned, and provided enough fibres reach their correct destination, good functional recovery is possible.

Neuropathy. A disorder of a peripheral nerve is called a *neuropathy*. There are many kinds. One of the most distressing is *trigeminal neuralgia*, again fortunately rare. The trigeminal or fifth cranial nerve has a motor and sensory territory on the face. In this condition there are paroxysmal episodes of extremely severe pain which may resist all treatment except destruction of the nerve itself with consequent facial paralysis and loss of sensation.

Bell's Palsy is the sudden loss of function of the seventh cranial nerve and there is again paralysis on one side of the face which usually recovers in time. Some bacterial diseases, especially leprosy, invade the nerves themselves. Chronic alcoholism may affect the nerves, as may diabetes, probably by interfering with the nutrition of the nerve cell. So may exposure to arsenic or lead or an unpleasant nerve poison which may contaminate cooking oil known as TOCP, or triorthocresylphosphate.

Muscular Dystrophies. These are a series of diseases of muscle in which there is progressive wasting and weakness of muscle, the causes of which are entirely unknown. They are divided up according to the age of onset and the muscles involved. *Duchenne's muscular dystrophy* occurs in the first decade of life. It affects most of the muscles eventually, including the heart muscle and those concerned with breathing, and so the outlook is not good. It is caused by mutations in DNA that block the body from producing a key muscle protein. Weakness in legs and hips spreads to the rest of the body.

The Muscular Dystrophy Group (Nattrass House, 35 Macaulay Rd. London SW4 0QP) gives great assistance to sufferers.

Myasthenia Gravis. This is a strange disorder of the mechanism which transmits instructions from nerve to muscle at the "neuromuscular junction," leading to extreme weakness.

Creutzfeldt-Jakob Disease causes fatal degeneration of the central nervous system. It may be sporadic, genetic or transmitted, and results from the accumulation of abnormally folded proteins in the brain. It is now clear that some cases resulted from eating animals infected with Bovine Spongiform Encephalopathy, BSE or "mad cow disease".

MENTAL ILLNESS

Conventionally mental illness is divided into two categories, **psychosis** (madness), and **neurosis** (exaggerated symptoms of commonly experienced states). Psychoses are themselves divided into: *organic*, implying that we can identify a physical cause, and *functional*, where the brain structure appears to be intact but its performance is abnormal. This division is now seen to be very blurred since there are physical diseases and drugs which can lower the threshold for response, or alter a person's perceptions so that he appears to be mad, albeit temporarily. The more research is done, the more organic causes are found for this behaviour.

Organic Psychoses: Dementia.

The organic psychoses result from actual damage to the brain. This damage can be caused by disease, as in syphilis; by tumours; by dietary deficiencies, as in inadequate vitamin B12 absorption; by poisons such as alcohol and lead; by drugs such as LSD or amphetamine; by problems of blood circulation such as heart failure or atheroma; and by genetic inheritance. The onset of illness can be either an acute confusional state or a chronic reaction known as *dementia*. The acute episode is characterised by an impairment of consciousness which may vary from difficulty in holding on to the point of a story, to actual coma. The chronic reaction, on the other hand, does not affect consciousness but intellect, memory and personality.

Memory for recent events is lost, while that for remote ones is preserved. About one in ten men and women over the age of 65 is likely to be affected. All GPs have now to be trained to detect the early signs of dementia. *See also* **Z59**.

Alcohol-Related Problems.

Since it is the most commonly and voluntarily ingested poison, it is worth giving a special mention to alcohol. Alcohol-related disabilities can be classed as social, psychological and physical. Social problems are often noticed first, and include failure to perform an expected role as parent or spouse or at work. Psychological difficulties include increased depression and personality deterioration. *Delerium tremens*, (DTs), is an acute confusional state involving intense fear and restlessness with hallucinations.

Most alcoholics experience blackouts ranging from momentary lapses to memory loss involving several hours. Intellectual impairment can occur and may be permanent. Physical problems associated with alcoholism include a doubled death rate, liver damage, gastritis, anaemia, increased rates of cancer, and infections such as TB. Sexual impotence is common. The children of alcoholic mothers are at increased risk of problems.

The Alcoholics Anonymous national helpline number is 0845 769 7555. Drinkline is a free and confidential service (the number is 0800 917 8282).

Schizophrenia.

Functional psychoses broadly fall into two categories: *schizophrenia* and *manic depressive psychosis*. Schizophrenia was a term introduced by Eugene Bleuler in 1911 to describe a group of illnesses in which there was a splitting of the psychic functioning so that the association between two ideas was bizarre, and mood seemed inappropriate to the circumstances. Nowadays schizophrenia is diagnosed on the presence of certain accepted symptoms such as a lack of insight, auditory hallucinations, unreasonable suspicions, a flatness of response *etc*.

Schizophrenia occurs in all societies. About one person in a hundred will develop the condition, and there is an increased risk where close relations are affected. Certainly, DNA mutations play a major role. Vitamin D deficiency also plays a part.

There are many theories of causation though an inheritance factor is clear, but there is argument about what this factor might be, and the extent to which its influence is affected by life events. Theories invoking abnormalities in the substances responsible for the transmission of signals within the brain itself are supported by the fact that some symptoms of schizophrenia can be induced experimentally. But as yet the physical theories are not wholly proven. Genes undoubtedly play a part and a genetic fault linked to the condition was identified in 2013. Over 100 genes play some kind of role in the development of the illness.

The 'double bind' hypothesis of Bateson, that an emotionally disturbed parent, who says one thing to a child but at the same time suggests a deeper, contradictory, message will cause the child to withdraw into a fantasy world, is another explanation. Whatever the role of early experience in causing schizophrenia, current stress brings on an attack.

Schizophrenia affects over 220,000 people in England at any given time. Many people are concerned that schizophrenia remains a 'forgotten illness'.

Treatment of Schizophrenia. This was revolutionised by the use back in the 1950s of phenothiazine drugs which not only tranquillise but also have specific anti-psychotic effects. The fact that schizophrenic patients are increasingly returned to their community, able to function, is due in large part to these pharmacological advances, and to the concept of 'milieu therapy' involving group activities, recreation and occupational therapies. Now, most people who have schizophrenia do not need continuous treatment in hospital.

Bipolar Disorder (**BPD**) (once known as **Manic Depression**) is characterised by swings of mood between depression and elation without apparent cause, and in this form is called the *bipolar* state.

More frequently, the disease is *unipolar*, showing only periods of depression interspersed with periods of normality. The difficulty in defining depression as an illness is firstly to distinguish it from a symptom, and secondly to make a distinction between normal and morbid depression which is depression of greater severity and duration than would be expected in a given population from the apparent cause. This last is a very subjective rating and this makes depression a difficult subject for research. The expectancy that one will suffer a depressive illness in one's lifetime is about one to three per cent, with females more likely than males. Generally it is accepted as a phenomenon of later life, but can occur at any age. In depression the major symptom is of a persisting sad, despairing mood, especially severe on waking up. Agitation or marked slowing down may be present, and hallucinations are not uncommon. Ideas of unworthiness, guilt *etc.* are frequent, loss of appetite, loss of weight, loss of sexual drive and loss of menstruation are also common. It is now thought that bipolar disorder and schizophrenia may be two versions of the same disease.

Causation of Depression. The cause is another area where authorities are in dispute, and theories abound. Early research pointed to learned helplessness as a cause. In experiments animals exposed to repeated stresses beyond their control, exhibited apathy, difficulty in accepting that they could do anything to help themselves, loss of appetite, and reduced sociability. The idea that depression is the result of aggressive feelings which cannot be channelled out and so are turned in on oneself, is a simplified view of what Freud said. Some support is lent to this idea by the fact that depressive illness is less common in time of war. Certain biochemical changes have been found in the brains of depressed patients, and the anti-depressant drugs work in ways to correct these imbalances, but whether these intra-cellular changes are cause or effect, and how this comes about, is still not entirely clear. Treatment is by specific anti-depressant drugs of which there are now many, by psychotherapy of various kinds, and much more rarely now by ECT.

Mania is a state of elation, hurried speech, and physical overactivity. Irritability is common if the patient is frustrated. Grandiose plans are made and money can be lavishly spent. Gradually as the illness progresses the sufferer becomes confused, angry *etc.* Treatment is usually by lithium.

Neurosis as we now understand it is a concept we owe to Freud, and to him, too, we owe the distinction between the neurotic disorders of *hysteria*, *anxiety* and *obsessionality*, and the disorders of *personality*. Those in the latter category, while having no detectable disease, are treated by psychiatrists as if they had, and this is a decision of society as a whole since the alternative is to refer such people to the legal or social services. Because the category of neurosis is so vague, it is hard to put a figure on how many people may be affected, but researchers in general practice consultations estimate about one in ten women, and half that many men are at risk. The reason for this disparity is not clear, but may be due to factors such as the greater freedom for expression of frustration enjoyed by men in our society than women. The majority of neurotic illnesses clear up, and may do so spontaneously, although obsessional and hypochondriacal symptoms are more persistent.

Anxiety Neurosis as a pathological state is where anxiety is either unrelated to a recognisable threat, or the degree of anxiety is out of proportion to the threat. The mechanism of our response to a threat appears to depend on the level at which the threat is perceived, if at a conscious level, the response is fear, if at an unconscious level, the response is anxiety. Symptoms include weakness, dizziness, sweating and tiredness. The physical symptoms are themselves unpleasant and increase the feelings of being threatened. Treatment may be by reassurance and explanation, by psychotherapy aimed at bringing the threat into conscious appraisal, or by drugs which are now widely, and often inappropriately, prescribed. *Phobic anxiety* occurs when unreasonable fear is focused on a particular object or situation, and leads to avoidance, Claustrophobia, fear of enclosed spaces, and animal phobias are well recognised. Social phobias, such as fear of eating in public or fear of vomiting are often harder for the sufferer to acknowledge. Phobic states are often associated with a traumatic event in the past, and avoidance through fear leads to a form of conditioning which reinforces the fear. Gradually the sufferer extends the range of feared and avoided stimuli. Behavioural therapy offers the chance to reverse this process.

Much is made of the manipulative nature of neurotics, and the idea of secondary gain, where the neurotic is perceived as getting the better of those around him by organising his, and other people's, lives to fit in with his symptoms. Certainly neurotic people can be very irritating in their demands, but their experience is one of personal suffering.

Suicide as a completed act has been on the rise in the UK in males since 2001, with the highest rates to be found in deprived areas. Every day 2 people under 25 die from suicide in the UK. Suicide is the biggest single killer of men between the ages of 20 and 45 in the UK. Lithuania has the highest suicide rate in the world. Worldwide one million people commit suicide annually, a 60% increase in 45 years.

Mental Illness in Childhood can refer to illness specific to children such as autism (*see below*), to emotional disorders, and to disorders of conduct. Because children are dependent on their families, much interest has centred on relationships within the family and on maternal deprivation as factors in the creation of childhood difficulties. The work of Bowlby highlighted problems consequent on the infant's need for attachment being denied, and he expressed the view that poor early experiences led to failures in later life to develop social relationships. Autism is a state where the child displays abnormalities of language, indifference to people, and ritual behaviour. Autistic children do not grow into schizophrenics, they grow up into autistic adults, and most remain severely handicapped. Phobias and obsessional behaviour are common in children and usually appear and disappear rapidly, especially with prompt intervention.

Depressive illness is rare before puberty and where depressive features are seen it is usually in response to environment.

Conduct disorders include persistent lying, stealing, disobeying, truanting, fighting or setting fires. The distinction from delinquency is important since the latter implies breaking the law which is quite common in adolescence. There is a high correlation between these behaviours and difficulty in reading.

Treatment is by assessment of the family situation, and by social and educational intervention.

Anorexia Nervosa is usually a disorder of adolescent girls in which food avoidance, weight loss, failure of menstruation and overactivity predominate. Anorexics often display a distorted view of their own bodies, being unable to see how thin they have become. The underlying difficulty may be a need to control something in their life at a time of actual dependence on parents, or an attempt to avoid the challenge of puberty and the demands, particularly of sexuality, that adulthood makes. Treatment is by behaviour modification, supervised weight gain, and psychotherapy. Anorexia has an appreciable death rate (it carries the highest death rate of any psychiatric disorder). A gene linked to the disorder has now been found. There are also suggestions that bacteria which confuse the immune system may play a part. Other patients may be permanently damaged. Today, anorexia is spreading among the very young. And anorexia among males is rising.

Bulimia Nervosa is a variant in which meals, often very large meals, are eaten and then vomiting is induced to get rid of them. It is 5-times more common in an urban environment.

Autism is a profound handicap which is now believed to be caused by brain malfunction linked to foetal hormone levels, often occurring with other disorders, including mental retardation, which affects three times as many boys as girls. It is almost entirely genetic in origin. The spectrum of the autistic condition encompasses dramatically different degrees of severity, varying from profound handicap through to subtle problems of social understanding in people of apparently normal or even superior intelligence. With the right therapy at an early age, continuing through to special education, autistic people can become less indifferent to others and can develop social responsiveness at a simple level. The disease is not irreversible.

There is no present cure for autism; and it is essential that people with autism are cared for in a special community by dedicated staff. It is thought that around 300,000 adults in the UK are autistic.

Asperger Syndrome (AS) is a form of autism. It is more common in boys. The National Autistic Society is a useful source for further information. Common inherited genetic variations that can contribute to autism were discovered in 2009, and a simple brain scan is now being developed to test for autism.

THE SKIN

The skin in the course of development before birth is particularly closely associated with the nervous system. It is therefore not surprising that so many skin diseases are influenced by emotional states. Other causes of skin disease are infectious, glandular disorders, vitamin deficiencies, and the numerous conditions for which no cause has been discovered, but which presumably are due to metabolic disorders.

Itching (or **Pruritus**) is one of the commonest skin symptoms. It may accompany many different general diseases, for example diabetes and jaundice. It may also be troublesome during the menopause (the change of life in women), in old age, or in nervous conditions. Sedatives and sex hormones sometimes help the itching during the menopause. Ointments may be useful.

Itching in the region of the anus and genital organs is relatively common. It may be caused by worms, by irritating vaginal discharge, or by sugar in the urine, as in diabetes. The alteration in the normal bacteria of the bowel which follows treatment with various antibiotics also often causes anal pruritus and soreness. In many cases however the itching has some psychological cause.

In treatment it is important to avoid ointments and creams which contain a local anaesthetic, because these substances can cause severe allergic reactions if used for longer than a few days, and may thus make the condition much worse.

Treatment with a local corticosteroid application is more effective and safer.

Scabies. Parasites such as the *scabies* mite or *lice* can cause severe and persistent itching. The scabies mite is very small, and since it burrows under the skin surface, is unlikely to be seen; it is the cause of itching most commonly between the fingers and on the front of the wrists. The itching is worst when the body becomes heated, as in bed. Treatment consists of painting the body from head to foot with benzyl benzoate application, followed the next day by a hot bath. Since scabies is contracted through close personal contact with an infested person it is desirable for all members of a family to be treated at the same time, even though only one of them is affected.

Lice are also specialists, one type of which affects the scalp, another the body, and a third the genital area. Head lice are destroyed by washing with shampoos containing organophosphorus insecticides such as malathion, body lice by insecticides and genital (pubic) lice by shaving off hair and washing. Obviously, the clothes, especially in the case of body lice, should be disinfested, by using a hot iron particularly over the seams, which lice (for some inexplicable reason) seem to favour. Apart from the discomfort they cause, lice are dangerous as potential carriers of typhus fever. Persistent lice need a prescription-only treatment to eradicate the problem.

Baldness, or Alopecia, is a very common and often distressing condition. Baldness is common in men and often hereditary. In the past, men have been sold a large number of ineffective treatments, but there are now some genuine treatments available. These include a lotion applied to scalp, minoxidil, or tablets, finasteride. For most men, no treatment remains the best option (although surgical hair restoration procedures are rising).

In 2011 the source of signals which trigger hair growth was discovered. These are stem cells within the skin's fatty layer. The discovery raises hopes of growing new hair follicles from these skin cells.

In women the hair often thins out soon after a pregnancy, but a few months later it usually returns to normal. Alopecia is a common side effect of drugs used in treating cancer, because these drugs affect rapidly-growing cells, such as hair follicles.

Seborrhoea is a condition in which there is overactivity of the sebaceous glands. The most usual form it takes is *dandruff*. However, it takes other forms, and those who have dandruff may also have rashes on the face, shoulders, and chest. In these areas there is a patchy, greasy, and often itchy, rash which does not clear up until the primary condition in the scalp is dealt with. The scalp should be washed with one of the modern sulphur-containing shampoos at least twice a week, and the affected parts on the face and chest can be dealt with by the use of a sulphur lotion (*not* on any account by greasy ointments).

Seborrhoea is not in itself difficult to treat, but since the condition depends on over-secretion of sebum, the skin lubricant, treatment may have to be persisted in during the years of early adulthood, when it is most active.

Scientists have decoded the DNA of dandruff.

Erythema Intertrigo is, quite simply, the sort of irritation which occurs usually from excessive sweating under the armpits, between the legs, and under the breasts in women. All that need be done is to wash frequently and to dust the affected areas after washing with powder. This is the condition which, in the tropics, is known as "prickly heat" and elsewhere as a "sweat rash."

Hyperhidrosis or **excessive sweating** is a problem in some people, especially when the sweating is accompanied with body odour. There is little need for anyone in these days to suffer in this way: for the cosmetic firms have produced many highly efficient deodorants which not only control odour but also control the amount of sweating.

Erysipelas is an infection of the skin caused by the haemolytic streptococcus. It begins as a red, raised area anywhere on the body where the germs have been able to enter through a small crack or cut in the skin. The red area advances and spreads over the body until the disease is got under control. Erysipelas is very infectious, and those who look after the patient should wash their hands thoroughly after contact. At one time the disease used to spread as an epidemic throughout the hospital wards, but this is very rare nowadays. Treatment is, of course, a matter for the doctor.

Chilblains used to be common in cold weather, especially in those with poor circulation. Ordinarily they occur in the toes and fingers. but may appear on the nose and ears. The part affected becomes swollen, dusky, and there is pain and itching, sometimes leading to ulceration. Protection of the body, especially the hands and feet, from cold is the best and the only really effective way of preventing chilblains. Warm lined gloves and footwear, and arm stockings or trousers should be worn outdoors. Adequate heating of rooms is essential: a temperature between 18° and 21°C is recommended. Most tablets, medicines, ointment, or creams for chilblains are useless. A skin affection caused by heat is rather grandiosely described as *erythema ab igne*, and used to be seen on the legs of ladies addicted to roasting their legs before the fire. It takes the form of red patches on the front of the legs.

Dermatitis (**Eczema**) means "inflammation of the skin," and therefore the word could be, strictly speaking, applied to any skin disease. In fact the term is used almost interchangeably with the term *eczema*. There are three main types of dermatitis or eczema. The first, *primary irritant dermatitis* results from injury of the skin by some powerful chemical, such as strong alkali or turpentine. The second, *contact dermatitis* is due to sensitisation of the skin to some substance which is normally liable to cause this type of allergic sensitivity; examples are nickel (in jewellery and suspender buckles), epoxy resins, rubber additives, primulas and chrysanthemums, and even ingredients of cosmetics. Contact dematitis may continue for a long time, even after the patient is no longer in contact with the offending material. The third type is often called *constitutional eczema*. Although the skin is apt to react adversely to various irritants and sensitisers the major part is played by the personality, and there is often a history of eczema, hay fever or asthma in the family. Treatment is more difficult, but local corticosteroids and tar, sedatives and psychological treatment can be of great help. A one-off job for eczema sufferers is being developed. Infantile eczema also belongs in this category, but in most patients it disappears as the child grows up. The National Eczema Society is based in London.

Remember, eczema is the itch you must not scratch!

Impetigo is an infectious skin disease caused primarily by the Streptococcus, but later often infected with staphylococci. It usually occurs on the face, and takes the form of blisters filled with pus on a red base; when the blisters burst their place is taken by yellow crusts. Impetigo is very infectious and easily spread by the fingers, dirty towels, or cloths; therefore, one of the first necessities is to prevent infection of others or reinfection of oneself by avoiding scratching and using a different towel each day, which must on no account be used by anyone else. Treatment is simple with an antibacterial ointment, so the main issue is prevention of contamination.

Urticaria or **Nettlerash** is a familiar skin disease in which itching weals appear on the skin, usually for no obvious reason. It is not infectious, and can be caused by nervous stress, certain drugs, allergy to some foods, or even exposure of the skin to cold. In some people it is possible to write on the skin with a fingernail: the "writing" appears in the form of weals. This is known as *dermographism*; it occurs in many normal persons as well as in many patients with urticaria. The antihistamine drugs are the most useful in the treatment of urticaria. Urticarial swelling of the tongue or throat requires urgent medical attention.

Acne, or "**Blackheads**," is a condition found on the face and shoulders; its appearance is so familiar that no description is necessary. Acne is one of those conditions which is the end result of many factors. There is, first, a greasy skin, the result of glandular upset (which is why the disease usually occurs in adolescence); secondly, there is infection of the skin; and thirdly, there is blockage of the sebaceous ducts, which ordinarily allow the grease from the skin to pass out on to the surface. Since the condition starts with excess secretion of grease, ointments should never be used, and probably the best applications are drying lotions containing some sulphur preparation which inhibits secretion of grease. The face should be frequently washed, and it is possible now to obtain detergent solutions which are both antiseptic and prevent grease formation. In severe cases ultraviolet ray treatment may be necessary. Advances are presently being made in the case of vitamin A in treating acne. Acne is now known to be linked to our genes. A new treatment is now being developed with a pill that rapidly dries out greasy skin.

Rosacea is when the nose and cheeks become red and greasy and the skin coarsened, occurs alike to chronic alcoholics and elderly ladies with no vices other than a preference for strong tea. Both cases are associated with indigestion, since, regrettable as it may seem, strong tea and alcohol are about equally liable to cause the gastritis which may be at the root of this complaint. However, in many patients the chronic flushing is caused in other ways and psychological factors are important. Sometimes in men enlargement of the nose may occur. Treatment is with oral tetracyclines.

Lichen Planus is one of the numerous skin diseases which seem to be due to nervous states of tension. It may occur on any part of the body, but is most common on the front of the forearms and legs. The rash takes the form of nodules which are lilac in colour and have a dent on the top; when these disappear a stain is left behind. There is severe itching. Treatment is a matter for a doctor, as it also is in the case of *psoriasis*, a very common disease of largely unknown origin, which is extremely resistant to treatment. It tends to run in families. It takes the form of slightly raised papules, usually on the elbows and knees; typically the papules are covered with dry, silvery-looking scales. Apart from the rash, the patient is usually in perfectly good health and there is no itching. Many drugs have been used in psoriasis, notably chrysarobin, and while it is not difficult to cause the rash (which may occur anywhere on the body) to disappear in one area or even in all areas for a time, it often returns.

Psoriasis. A skin disease which results in patches of inflamed, red skin often covered by silvery scales. It is at present a long-term condition.

Warts, or **Verrucae** are both familiar enough. They are caused by a virus, and are, theoretically at least, contagious. Usually they are found on the hands, but may occur elsewhere. Treatment is best carried out by a doctor, who will use a cautery, a caustic carbon dioxide frozen into "snow." A curious feature of the common wart is that it can sometimes be caused to disappear by suggestion.

Different altogether from the common wart is the *plantar wart*, which occurs on the soles of the feet and causes a good deal of discomfort. It is best dealt with by a chiropodist or in bad cases by a skin specialist since it is highly infectious.

Ichthyosis is a disorder of skin formation with which some unfortunate people are born. The oil and sweat-producing glands do not function well and the skin is dry and scaly like the skin of a fish. It is, however, possible to help the condition, which does not affect the general health, by frequent alkaline baths to wash off the scales, and the subsequent use of lanolin to replace the lacking oil. Large doses of vitamin A often seem to help.

Skin Cancer. Squamous cell skin cancers occur mostly in old people. They are most common on the face or hands, and usually appear as a nodule which breaks down and produces an ulcer. The glands may later be affected, but such cancers can almost invariably be cured unless a considerable time has elapsed during which they have been neglected. They are much more common in persons over-exposed to the ultraviolet in sunlight, and there is great worry that their frequency will increase as the ozone layer of the atmosphere becomes more depleted. Great care should be taken in direct sunlight, especially when sunbathing.

Cases of skin cancer have recently proliferated, probably as a result of global warming which may make time spent in the sunshine more dangerous. Package holidays have also played their part. The risk of developing skin cancer from using sun lamps has trebled in the last 15 years.

A pill to target a faulty gene in malignant melanoma (the deadliest form of skin cancer) has heralded a major breakthrough. Scans can now also be used. Nowadays, 80 per cent of skin cancer sufferers survive. Mortality rates are higher in men than women. A combination of immunotherapy drugs has also proved highly effective.

Basal Cell Skin Cancers were also known as "rodent ulcers", because untreated they act by eating into the tissues in the area where it has started. X-ray therapy or operation is necessary, but the outlook is good. *Cysts* on the skin are due to blockage of the sebaceous glands. They may become very large, and are best removed, as they may become infected. They do not turn into cancer, and there is no such thing as "male" and "female" cysts. It does sometimes happen that *moles*, especially of the bluish-black type, may become malignant, forming a cancer called a *malignant melanoma*. This is a fast growing and extremely dangerous cancer. Any change in size or shape of any mole must be shown to your doctor immediately.

Skin Grafts.

These are a complex subject. They are used basically for a number of conditions in which large areas of skin have been removed from the body, as in burns or serious accidents. In other cases, as in plastic surgery, grafts may be used to make a new nose, eyelids, and so on. The following are the main types:

Split-thickness Grafts are grafts removed from another part of the body by an instrument known as a dermatome, which cuts sections *c* 10 by 20 cm. containing part of the deep layers of the skin.

Full-thickness Grafts are when the whole thickness of the skin is removed from elsewhere and applied to an area which has to bear friction or heavy weights (*e.g.* hand or foot).

Pedicle Grafts are rather difficult to describe. Briefly, if for example, one wants to make a new nose, one cuts an area of skin and underlying fat about 5 cm wide and 12·5–15 cm long in the abdomen. One end, however, remains attached so that it gets adequate blood supply. The problem is how to get this tissue to the nose, and this is done by a complicated process of leap-frog. First, the free end of the graft is attached to the forearm, whilst its "root" remains in the original site, and when it begins to grow and get its blood supply from the arm, the original "root" is cut. So we now have a "sausage" of tissue attached to the arm. The arm is then lifted to the face and kept firmly in position there until the new free part becomes attached. It is then detached from the arm, modelled to the correct shape, and grows where the nose was.

THE JOINTS.

Rheumatism is a word most doctors wish did not exist. This is partly because it is used for a hotchpotch of diseases, in all of which there is pain and stiffness of what is called the musculo-skeletal system, *i.e.*, the muscles and the joints. It may mainly involve the joints, in which case it should be called arthritis; or it may involve other structures near the joints like tendons, muscles and fibrous tissue. Joints may either suffer from inflammation or degeneration or both, and the trouble may be acute or chronic or both; so it is easy to see what a mix-up the subject becomes, especially when we must include the joints of the spine as well as the limbs, feet and hands.

A good deal of arthritis used to be due to various germs, but these types are much less common now that the infections causing them have become rarer or better treated. They used to include gonorrhoea, tuberculosis, septic joints, syphilis, brucellosis, typhoid fever, dysentery and so on.

The importance of *rheumatic fever*, which is a reaction to an infection (streptococcal sore throat) rather than being actually caused by the Streptococcus, is not because it involves the joints. This arthritis quickly clears up, but there may also be disease of the heart (*see* **Z27**).

Rheumatoid Arthritis is a completely different condition in which there is non-infective inflammation of connective tissues throughout the body. In the joints, the normally smooth, lubricated synovial membrane lining the joint cavity becomes scarred, leading to distortion, especially of smaller joints like those of the hand. Another characteristic feature is its capacity to vary in severity from time to time, with a strong tendency to unexplainable periods when it gets better or worse. This makes it extremely difficult to know whether any form of treatment is being useful, since any response may have occurred in any case. As in all diseases which behave like this, especially those in which medical men are also baffled, there are almost as many theories and treatments as there are doctors. It has never been satisfactorily shown to be caused by infection, faulty nutrition, "glands," emotions or personality disturbance, nor is it convincingly inherited. The best current theory links it with an increased sensitivity reaction, perhaps to the body's own tissues, known as "autoimmunity." From the patient's point of view there is swelling and deformity of the joints with tenderness on pressure and pain on movement. Treatment involves a lengthy and complicated regime of rest, relief of pain with anti-inflammatory drugs such as aspirin, exercises and the application of heat, with attention to general physical and mental health. At some stage adrenal corticosteroids (cortisone and its derivatives) are often tried, but although these can give great relief they have to be very carefully used to avoid very unpleasant side-effects. Today, around 400,000 adults (and children) in the UK have this agonising condition.

Osteoarthritis is another completely different condition closely related to the normal processes of ageing. Therefore it occurs in older people and tends to be in larger, weight-bearing joints of the spine, hips and knees rather than in the hand; although the end joint of the fingers is commonly affected. Hard wear and tear, especially that caused by overweight, or injury may be the beginning of it. It is *not* due to diet, and dieting has no part in treatment except in those who need to slim. Physiotherapy, including heat, is helpful. It is not such a relentless condition as rheumatoid arthritis and patients should be reassured about this. It is partly inherited and is the most common form of arthritis.

Around six million people in the UK suffer this pain in one or both knees (often from wear and tear on the cartilage). Readers may also wish to refer to www.arthritiscare.org.uk

Osteoporosis is a reduction in bone density with-out change in the chemical composition of bone, and has many causes including hormone imbalance, poor diet, age and long use of corticosteroid medicines. Hormone replacement therapy after the meno-pause is partly to prevent osteoporosis. Around 3 million people in the UK suffer from osteoporosis, with a heavy annual toll of hip fractures, wrist fractures *etc.* A new treatment is with bisphosphonate medication.

Fibrositis (now more usually called **Fibromyalgia**) and other painful forms of "rheumatism" are very often manifestations of psychological problems.

Backache. A symptom which may be caused by many different diseases—sometimes disease of the vertebrae themselves, sometimes strain of the ligaments, and sometimes inflammation or spasm of the surrounding muscles. "Lumbago" is usually due to inflammation of the muscles in the small of the back. Backache from purely local causes may be treated temporarily by applying heat in the form of a kaolin poultice or a rubber hot-water bottle and taking painkillers. On the other hand, many cases of backache are due to disease elsewhere, so a doctor should be consulted. BackCare is the name of the National Back Pain Association.

Gout. An excruciatingly painful arthritic inflammation of the joints (especially the toe) caused by crystals formed by uric acid. Chronic gout can be avoided by such medication as allopurinol. Gout can lead to kidney stones. Cases of gout, which are most common in men, are rising very rapidly. It is increasing common in people in their 20s and 30s. Obesity is blamed, although gout is known to run in families.

EYES AND THROAT.

Eye Diseases. These are very specialised and only very general information can be given here. The most common is inflammation of the conjunctiva causing redness and usually due to infection or some irritant substance or dust. If it persists and leads to hard crusts of yellow pus on waking in the morning, get it seen by a doctor for treatment probably with antibiotics. First-aiders are usually instructed how to remove small particles of grit from under the lids. (*see* **Z20**).

Remember the eyes are part of the brain: the only visible part. Perhaps this is why people's eyes are so revealing. (*See* **Special Topic Z57**).

Sore Throats are a nuisance we all have to put up with from time to time. If they last more than a few days they should be treated professionally. Never prescribe antibiotics for yourself, especially in lozenge form, and only expect your doctor to give them if other measures fail.

Tonsils and their inflammation may be a problem. It is comparatively rarely that they should be removed. Of course there are many children who benefit so much from having tonsils out that the operation (which has real dangers) is worth doing. But please allow your doctor to decide.

DISEASES OF WOMEN.

Internal Sexual Organs. These, as with the urinary system, can best be described as shaped like a capital Y. At the tips of the arms of the Y are the female sex glands, the ovaries: the two arms running downwards are the Fallopian tubes: the point where the arms meet is the womb or uterus: the single leg of the Y is the vagina. These are the *primary sexual organs* of a woman and they undergo regular cyclical changes in response to the control exercised over them by the pituitary gland, situated in the base of the skull. This control is mediated by chemical messengers (hormones) secreted into the circulation. The ovaries also secrete hormones, oestrogen, and progesterone, and a delicate hormonal balance is maintained between the pituitary gland and the ovaries. Each month an egg cell (ovum) matures and is released from the ovary, usually midway between two menstrual periods: the ovum is wafted along the Fallopian tubes by waves of contraction and if fertilised embeds in the lining of the uterus which has been conditioned to nourish it by the ovarian hormones.

If it is not fertilised the ovum escapes from the uterus, altered hormone levels then cause the lining of the uterus to be shed (this is menstruation), usually about 14 days after ovulation. After menstruation a new cycle begins; another ovum matures and a fresh lining grows in the uterus. These changes recur from puberty to the menopause.

Menstruation does not occur during pregnancy, of which a missed period is often the first sign. However, women do miss periods even though they are not pregnant, and this usually means that some minor and temporary change has occurred in the hormone balance. If three consecutive periods are missed it is wise to consult a doctor.

The Breasts are called *secondary sexual organs* and are also under the influence of the ovarian hormones. Two conditions which need treatment are *mastitis* and *cancer of the breast*, both of which are characterised by lumps within the breast tissue.

Mastitis may be uncomfortable but is not dangerous and can be treated medically, whereas cancer is more serious. The distinction between mastitis and cancer can only be made by a doctor and any woman who discovers a lump in her breast must seek medical aid *at once*. Although death rates from breast cancer fell in the 1990s (partly due to use of the drug tamoxifen) breast cancer has now overtaken lung cancer as the commonest cancer. The lifetime risk of breast cancer has now increased from one in 9 to one in 8.

Lifestyle factors, such as alcohol and obesity, are partly to blame. All women may soon be offered a genetic test (possibly a simple mouth swab) which would tell them if they were likely or unlikely to contract breast cancer. One in three women who get breast cancer are over 70. The drugs tamoxifen and raloxifene are now available for women with a family history of cancer.

Abscesses also occur in the breast, nearly always when the mother is feeding her child. Here again, a lump appears, the breast becomes red and very tender, and the woman may be feverish. Treatment with antibiotics is sometimes successful, especially if the mother consults her doctor quickly, otherwise treatment is by a small operation.

The Ovaries. The two commonest diseases of the ovaries are cysts and disorders arising from hormonal imbalance. The symptoms of ovarian disease are usually abdominal or low back pains, and heavy and painful loss during the periods, which may become irregular. These signs should be taken as a warning to consult a doctor. *Ovarian cancer* is also a very real danger (each year 6,500 women in the UK die from this disease). A gene which raises the risk of ovarian cancer has now been identified.

The Fallopian Tubes. Infection of the Fallopian tubes is called salpingitis. The membrane lining the tubes is continuous with the lining of the uterus, hence an infection is rarely confined to a circumscribed area in either the tubes or the uterus, and pelvic inflammatory disease is a better name for this condition. Pelvic inflammatory disease often follows an abortion, or childbirth where part of the afterbirth (placenta) has been retained, or can spread from an infection in a nearby organ, for example the appendix. Infection is sometimes conveyed by the blood from another septic source in the body. The gonococcus is another cause of infection. The disease is characterised by pain and tenderness in the lower part of the abdomen, accompanied by fever, general malaise and frequently (but not invariably) a vaginal discharge. The treatment of pelvic inflammatory disease is usually medical and is the same irrespective of the primary site of infection. Before the era of antibiotics the disease often became chronic and the Fallopian tubes were frequently blocked by a cicatrising scar, a cause of subsequent sterility.

The Uterus. This is a hollow muscular organ and both its musculature and its lining membrane can be the site of disease. *Fibroids* are non-malignant muscular tumours which develop in many women. The main symptom is a heavy menstrual loss and surgical removal of the uterus (hysterectomy) is often necessary. This can be a major operation, but trans-vaginal hysterectomy, which does not involve opening the abdomen, has made this operation much less daunting. Hysterectomy does not impair sexual pleasure, but no more babies can be conceived. Infection of the lining of the uterus is usually part of a generalised pelvic inflammatory disease (*see* Fallopian tubes).

For those women who lack a viable womb to bear children, medical science is on the verge of providing uterine transplants.

There has been a massive jump in cases of womb cancer, fuelled by a rise in obesity. Around 9,000 women in the UK are now diagnosed annually, up from 4,800 20 years ago.

Cancer of the Uterus (Cervical Cancer). The uterus is pear-shaped and consists of a body and neck. The wide end is uppermost (the body) and the narrow neck (cervix) projects into the top of the vagina. Cancer of the cervix is commonest in middle-aged women who have married young and have had a large family; cancer of the body of the uterus usually occurs after the menopause and is more common in nulliparous women. The symptoms are variable and it is sufficient to emphasise that any woman who has unexpected bleeding, especially after intercourse, whether her periods have stopped or not, *must* see her doctor at once. Cervical cancer is the second commonest cancer in women. A simple urine test may soon be used to screen for cervical cancer.

Cancer Screening. All the treatment depends on individual circumstances, but is usually by operation. It is now possible to detect cancer of the cervix long before symptoms develop and at a stage when the disease can be eradicated by a relatively small operation. This early detection has been made possible by the development of exfoliative cytology. Cells taken from the cervix (without discomfort to the woman) are examined under a microscope. This test is popularly known as the "cancer test" or "cervical smear." A cervical smear is often taken as part of the routine gynaecological examination by consultants, general practitioners, and family planning doctors, and a nationwide screening programme is now in force. It is a big step forward in preventive medicine and may ultimately solve the problem of cancer of the cervix. Every woman between the ages of 25 and 60 should have the test done at least once every 5 years.

A vaccine for cervical cancer was approved for use in the UK in 2006. In 2008, it was decided the HPV vaccination should be offered to all girls aged 12–13 in the UK. The programme has now been extended to those aged up to 18.

Prolapse means a sagging down of the uterus into the vagina and the cervix may even appear at the outside. It is a result of frequent childbirth and laxness of the ligaments which support the uterus: weakness of the vaginal walls often occurs at the same time. The symptoms of uterine prolapse are low back pain and a heavy dragging feeling in the lower abdomen: these are often overshadowed by the distressingly embarrassing incontinence which results from lax vaginal walls. The stress of only a sneeze, a cough, or a giggle often causes the involuntary escape of urine. The cure is operative and very rewarding.

Dysmenorrhoea or pain with the periods, is very common and most women experience this symptom at some time or another. Very often a girl's first periods are troublesome, but dysmenorrhoea develops after a year or two: this suggests that a psychological element is involved. The sensible thing to do, if pain is troublesome, is to see a doctor.

Amenorrhoea means stopping of the periods in a young woman. It may signify pregnancy or glandular disease or it can be purely psychological.

Menopause occurs when the ovaries no longer have any egg cells to release, causing the cessation of the normal menstrual cycle (*see below*). The hormones oestrogen and progesterone are no longer produced, and this change is often accompanied by "hot flushes". Over time women also experience a loss of bone strength (osteoporosis). It was hoped that giving these missing hormones by mouth would improve women's health. However a recent study of 27,000 women showed "**hormone replacement therapy**" caused a small increase in heart attacks, stroke, pulmonary embolus and breast cancers (with one extra such "event" occurring per hundred women treated for five years).

Abortion means the death and expulsion of a foetus before the 24th week of pregnancy. Abortion may happen spontaneously (*i.e.* naturally) or be deliberately induced. If deliberate, it may be legal or illegal (although a woman who aborts herself commits no offence) and the Abortion Act 1967 defines those conditions in which abortion is legal. The two main symptoms of abortion are bleeding and abdominal pain. Any bleeding occurring during pregnancy ought to be reported at once. Pain starts in the back and lower abdomen and is usually spasmodic in character, and like colic it works up to a peak and then temporarily passes off. Any pregnant woman with pain and bleeding should go to bed at once and send for her doctor. When doctors are convinced that a pregnancy should be terminated then an abortion may be performed in hospital.

CONTRACEPTION AND FAMILY PLANNING

In today's world, advice and help on all aspects of contraception and family planning are readily available. Many people will start with their local GP.

In addition, there are helpful websites of such organisations as the Family Planning Association (www.fpa.org.uk) and Marie Stopes International (www.mariestopes.org.uk).

DRUG DEPENDENCE

Dangers of Drug Use.

1. **Toxic Effects**. The drugs which act upon the nervous system, like any others, have characteristic toxic or unwanted effects of their own (incidentally, these may become apparent rapidly; even, on rare occasions, after only a single dose). Such effects may have little or nothing to do with the desired effects for which they are being prescribed and taken. For example, aspirin is liable to cause bleeding, which is occasionally serious, from the lining of the stomach in a large proportion of people who take aspirin regularly. Some drugs may cause rashes and other allergic reactions in susceptible subjects; and jaundice, fainting, tremors, *etc.* are known to occur in some patients taking a variety of other drugs.

2. "**Rebound**." The human body works in such a way, over a variety of its activities, that it tends to return to a "neutral" position after it has departed from this for any reason. For example, over-eating tends to be followed by a lessening of appetite, at least for a time; the runner makes up for his air-deficit during the race by breathing more deeply thereafter; and if, at rest, you breathe for a time more rapidly and deeply than you need, this period will be followed by one in which you breathe *less* often than usual until the balance is restored. These illustrations—and there are others—have nothing to do with drugs; but in a similar way, it seems that if a continued pain, or an unpleasant emotional state such as anxiety or depression is changed into its opposite, or removed altogether by the use of a drug, the prior state may return with increased force when the drug is no longer taken. The "rebound" phenomenon, naturally, encourages the patient to take another dose, and so on.

3. **Habit Formation**. This alternation of mood-changed-by-drug with the disturbed mood itself leads to the habit of taking the drug. The patient comes to rely upon it and to take it anyway, even before the unpleasant state has returned. At this stage he is said to be "habituated"; he has a psychological need for the drug, and later may become disturbed at the possibility that it will not be available when he needs it. This might not matter so greatly, if it were not that continued use of drugs in this way has physical consequences.

4. **Tolerance and Habituation**. The body also tends to restore its own balance when drugs are given, too. It "learns" surprisingly quickly how to deal with substances with which it has never before been confronted, so that it eliminates subsequent doses more and more quickly and completely. Thus the effect of each successive dose is smaller and lasts for progressively shorter periods of time. To counter this, the patient tends to increase the dose: and the vicious circle continues. At this point he has become physically dependent upon the drug: and he may suffer physically—sometimes so severely that he dies—if supplies are not continued.

5. **Lethal Dosages**. As he increases the dose in this way, so his tolerance of its effects increases, to such an extent that after prolonged use he may be taking doses of a drug that are five or ten times greater than those which will kill somebody not dependent upon them in this way. It sometimes happens that a patient develops a renewed craving at some point after a course of treatment, in which the dose of drug has been reduced without removing the underlying cause of his dependence. He may then obtain and use the dose he habitually took before treatment, not knowing that his body will have lost its tolerance of such doses. That dose is now as high for him as for any other person and so may be lethal. There has been a number of deaths for this reason.

Factors in the Causation of Dependence.

The risk of becoming dependent upon a drug is governed by three main factors; the drug itself, the personality of the individual who takes it, and the circumstances in which it is taken.

Most adults have taken alcohol at one time or another, yet *relatively* few are dependent on it (relatively few, but many too many; more than a million in the United Kingdom alone).

Many of us have had morphine or some other strong analgesic for medical reasons, without becoming dependent upon it. However, if we start to take such a drug "for kicks"—as more and more people, particularly teenagers and young adults are doing—it is extremely probable that we shall become dependent upon it.

It is also probable that each one of us would become dependent, were he or she obliged to take it regularly, for long enough, and in sufficient dosage. Thus, although there are personalities—psychopathic, immature, or unstable—that are more prone than others to become dependent if they are exposed to the drug, there are also drugs that are more likely than others to cause such dependence no matter to whom they are given. The extent of the dependence will vary; with some, it is never physiological but remains psychological (but not the less real or disturbing for that). Also, the rate at which dependence develops may vary; and the picture presented by the dependent subject—the extent to which his normal life is impaired, or to which he becomes dangerous to himself or others—varies as well. In a very much oversimplified way, some of these relationships will now be summarised for certain substances.

Types of Dependence.

Heroin, morphine and cocaine are usually injected (with all the risk this implies). Amphetamines ("Benzedrine") are tablets or capsules, and marijuana ("reefer," hashish) is smoked in cigarettes. Heroin and cocaine are now usually taken together. Combinations of drugs often act differently from their individual constituents and patients dependent upon them are even more difficult to treat. The most used drugs in Britain today are ecstasy, cocaine, cannabis and skunk, poppers, speed, meths *etc*, but "legal highs" (which mimic the effects of banned drugs) have surged. These "legal highs" such as meow meow, Spice and Black Mamba have now been banned, but others such as AMT are still legal. They are known as New Psychoactive Substances (NPS).

Psychological Dependence is considerable with heroin, morphine, cocaine, and amphetamine, but much less with marijuana.

Physiological Dependence is great with heroin and morphine, less with barbiturates, alcohol, and amphetamine in that order, and virtually nil with cocaine and marijuana. Personality plays a greater part in initiating dependence on alcohol, marijuana, and barbiturates than with the others. Heroin, cocaine, and morphine are the cause of more antisocial tendencies in dependent people than alcohol, barbiturates, and amphetamine.

One danger of marijuana is that the search for it will lead the searcher into localities where his risk of exposure to even more dangerous influences is greatly increased. It is thus sometimes argued that if it were legal to consume marijuana, the number of young people who yearly become dependent upon the other more dangerous drugs would in fact decrease. There is as yet no evidence for or against this proposition. The number of drug dependent people in the UK is rising fast for heroin, crack and cocaine. and the number of drug deaths in Britain is now among the highest in the world relative to our population.

This number is very large for alcohol (many doctors believe we are in the midst of an alcohol crisis, with all its implications for the NHS) The number of alcohol-related admissions to hospital in England topped a million a year for the first time in 2010 (double the 2002 number). By 2015, alcohol abuse by older women was a serious cause for concern. Very few people are dependent on morphine.

Treatment.

Exhortations, imprisonment, and other moralistic or legalistic approaches are useless. Treatment of any person dependent upon a drug is a matter for a qualified psychotherapist. It is liable to be time-consuming and frustrating for patient and doctor, and it is sometimes unsuccessful. At present, there are too few specialists or centres where treatment can be obtained, although it is to be hoped that this situation will change as the problem is increasingly seen by our society to be of exceptional gravity.

When there is little or no chance of cure, prevention is certainly the best treatment. Drugs should only be taken on the prescription of a doctor: and the patient should remind him from time to time, if this be necessary, that he would like to dispense with his drugs as soon as the doctor thinks it possible.

PART III. SPECIAL TOPICS

THE HUMAN EYE

Light enters the eye through the *cornea*, which coarsely focuses light onto the *retina* at the back of the eye. The light is finely focused by the *lens*, the shape and focussing power of which is controlled by the *ciliary muscles*. To see distant objects these muscles relax and the lens flattens. With age, the lens loses elasticity and it becomes more difficult to focus. The amount of light entering the lens is controlled by the *iris*, which closes the *pupil* in bright light or to improve image quality for close objects. We can see finer detail when the pupil is small. This is contrary to, say, a camera because of imperfections in the cornea curvature. This makes it more difficult to see distant objects at night.

The Retina

The retina contains three types of light-responsive cells, of which *cones* and *rods* are used for vision. The cones are responsible for our perception of colour and come in three types, respectively most sensitive to blue, green and yellow light. In combination, we can see the full range of colour from violet to red, although the precise endpoints of this range vary from person to person. (Other animals see very different colours, for example bees see the spectrum from ultraviolet to orange.) The cones are most sensitive in bright light, whereas the rods allow vision in dim light. Because the rods cannot distinguish between colours, faint coloured objects, such as stars in the night sky, appear black and white. Perceived colours depend on both the cones activated and on contrast, background colour and psychological factors. Pilots can perceive a blue sky to be grey as there is no edge to the colour.

The rods and cones are not evenly distributed. The cones are largely in the *macula*, the middle of the retina, with the rods being entirely absent in the one-third millimetre sized *fovea* at its centre. As a consequence, stars that are too faint to activate the cones are only visible when off-centre in our field of vision. There are far fewer blue cones - and none in the fovea – so very small objects can appear colourless.

The Absorbtion of Light

In the rods and cones, light is absorbed by a chemical called *rhodopsin* (part of which is vitamin A) and generates an electrical signal. Further cells in the retina combine the signals from adjacent rods and cones in order to identify contrast and orientation. These processing cells are unfortunately located in a layer in front of the rods and cones, which degrades the image before it reaches the light-responsive cells. The exception is at the fovea, where the processing cells are shifted to the side and the eye consequently has its greatest *acuity* (ability to resolve small objects). We therefore move our eyes, along a line of print for example, when we need high acuity.

The Optic Nerve

The processing cells produce signals that are transferred to the *visual cortex* in the brain along the *optic nerve*, which exits the retina at the *blind spot* and where there are no light-responsive cells. In the visual cortex, the information from the two eyes is combined and different neurons are activated according to the orientation, depth, motion and colour, for example, of the object that the eye is seeing. We have two eyes with overlapping fields of vision so that we can perceive how far away an object is located, in combination with object familiarity, texture, motion *etc*. Many other animals have a 360 degree visual field but with no (or less) overlap between them.

Other Eye Structures

While vertebrates (animals with skeletons) have broadly the same type of eye as us, invertebrates have different structures with one exception: the octopus. Remarkably, the octopus eye evolved completely independently and yet developed an eye with all the same features and one major improvement: the retina is "inside out". This means that the light reaches the light-responsive cells without having to first pass through the other processing cells in the retina.

The third light-responsive cell type, only discovered in the last few years, forms a web-like structure on the retina and is not involved in vision. The electrical signal from the active chemical in these cells, *melanopsin*, controls the body's circadian rhythms, such as the sleeping and waking cycle, and is thus important in recovering from jet lag. In some other animals, these rhythms are derived from light entering the brain directly, bypassing the eye.

Spectacles and Contact Lenses

In normal vision, light from an object is focused to a point on the retina. For people with *myopia* (short-sightedness) or *hyperopia* (long-sightedness) however, light focuses to a point respectively in front of or behind the retina. With *astigmatism*, light is focused to a line instead of a point, due to asymmetry in the lens. These problems may be corrected by appropriate lenses, either spectacles or contact lenses.

More complex spectacles - described as bifocals, trifocals and varifocals – focus at two or more different distances, suited to common tasks such as reading, in separate regions of the lens. These regions are usually located such that distant objects are viewed through the top part of the lens, but alternative arrangements may be more appropriate for plumbers, for example, who need to see overhead. Some lenses have their near focus set for computer usage, where the distance between the eye and the screen is typically 70 centimetres, rather than reading (40 centimetres). Glasses are also available with photochromic lenses, which darken when they absorb ultraviolet light from the sun. Antireflection coatings on the glass may be used, particularly to provide eye protection from ultraviolet light following corneal replacement.

Advantages of Contact Lens

Contact lenses, in addition to their cosmetic benefit, have several optical advantages over spectacles. A contact lens traps a tear layer between it and the cornea, correcting for irregularities in the corneal surface. In addition, correcting extreme short- or long-sightedness with spectacles uses their optically inferior periphery, a problem which is avoided by contact lenses. Contact lenses come in hard and soft versions and are made from material which allows oxygen to pass through. Although bifocal contact lenses are available, they are difficult for the eye to adapt to and hence separate lenses in each eye for near and distant sight are generally used instead.

Common Vision Defects

Nearly a tenth of males have some *colour blindness* because one of the three cone types is either missing or is sensitive to a slightly different colour from normal. A very small number of people see only in black and white because they have no cones at all. Less commonly, colour blindness is due to damage within the optic nerve or brain.

People with *ambylopia*, or lazy eye, have one strong eye and one weak eye because their vision did not develop normally during childhood. The brain will rely on only one of the two eyes if there is a significant difference between them through damage, unequal focusing or *squint*, leaving the other to become lazy. Ambylopia can often be corrected while the eye is still developing, sometimes simply by the child wearing a patch over the good eye to force the other to strengthen. With squint, the two eyes look in different directions causing double vision and a loss of depth perception. It can often be corrected by surgery to the muscles controlling eyeball movement.

Floaters are the spots and strings superimposed on our vision and which drift around as the eyeball moves. They are strings of the protein collagen in the vitreous, the fluid filling the eyeball, and cannot be safely treated without risking sight.

Myopia is the term for short-sightedness and it is becoming an epidemic, perhaps due to lack of sunlight.

Age-Related Vision Problems

While population longevity continues to increase, the eye is not keeping pace and age-related vision impairment is therefore becoming more widespread. Generally, during childhood, the eye becomes increasingly myopic; later in life, there is a tendency towards long-sightedness. The lens thickens and allows less light through: the infant lens transmits more than 25 times more violet light than a 70-year-old lens. It loses its elasticity and so the eye becomes unable to change focus, a process called *presbyopia*. In any case, the eye becomes unable to see fine detail or realise that a light is flickering. There is a loss of contrast due to increased scatter within the eye. In particular, this causes increased glare when the eye sees a high variation in brightness, for example when driving at night. The visual system becomes less sensitive, both at the retina and in the brain, leading to a reduction in colour discrimination, depth perception and the size of the visual field. However, changes in light transmission and relative cone sensitivity can be compensated for by the brain.

There are a number of sources of partial and total blindness that are principally age-related:

Macular Degeneration (MD), as the term suggests, is retinal damage in the centre of the field of vision and may appear in sudden or gradual forms, causing difficulty in seeing fine detail such as print. The rarer, sudden degeneration can be impeded by laser photocoagulation, a process which seals the local blood vessels. Macular degeneration cannot be reversed but its effects may be mitigated by retraining the eye to treat the macula as a second blind spot. In the UK around 250,000 people are registered visually impaired because of MD.

MD occurs when the layer of the retina responsible for nourishing the macula's light sesitive rod and cone cells, and for carrying away waste products, starts to function less effectively.

Cells in the macula break down, causing loss of sight in the central part of the field of vision but leaving the side vision, known as peripheral vision, unaffected. A new class of bionic eye implant may soon aid this problem.

Diabetic Retinopathy is where the blood vessels feeding the retina are weakened and consequently cause retinal damage, such as detachment. Again, photocoagulation is used for treatment. If the retina has detached or blood has entered the eye, it may be necessary to replace the vitreous. It is vital for diabetics to be monitored for this condition.

Cataracts. A *cataract* is a loss of lens transparency, causing blindness. The lens in a young person strongly absorbs ultra-violet light, usefully preventing it from reaching the retina. With age, however, the lens yellows. It increasingly absorbs visible light as well and eventually cataracts. Diabetes and trauma can also cause cataracts. It is a particular problem in developing countries, where it tends to occur earlier in life – around fifteen years earlier in India than in the USA. Today, it is a routine operation to remove the lens and insert a fixed-focus lens implant to restore sight. While implants with multiple fixed foci are available, patients experience reduced contrast as in-focus and out-of-focus images are always superimposed on the retina.

Now, eyedrops that may cure cataracts are being developed, so avoiding surgery (an estimated 300,000 cataract operations take place annually in the UK).

Glaucoma is damage to the optic nerve. The nerve cells die, usually because the pressure within the eye is too high. The condition is irreversible so early detection is vital. It is controlled using drugs or surgery to reduce the pressure.

Glaucoma is the second largest cause of blindness in the UK, affecting up to 500,000 people (many of whom do not realise they have it).

Eye Tests

The optometrist uses a variety of tests both to measure the eye's error in focusing and to look for evidence of the diseases and defects described above. Test charts and instruments such as the retinoscope are used to measure the eye's focusing ability and determine the appropriate spectacle strength for a patient. A photograph of the retina is used to look for visual signs of damage, including the blood vessels feeding it and the optic nerve at the blind spot. Measurement of the pressure within the eyeball, to test for glaucoma, is done by observing how well a jet of air directed at it is reflected back. The size of the visual field, and the location of any blind spots within it, is tested by flashing a series of separated bright lights and the patient indicating which they can see.

Laser Surgery

The most common use of lasers in medicine is in eye surgery. To remove cataracts or reshape the cornea, light from a laser is used to cut the tissue more precisely than a knife is able to by either breaking the chemical bonds or ionising the structure. Reshaping may be performed either on the cornea's surface or, by cutting open a flap, its interior. It cannot be used to restore the eye's ability to change focus.

FOCUS ON DEMENTIA

Literally 'out of one's mind', dementia is an umbrella term for a set of symptoms which occur when the structure of the brain is damaged in some way, leading to a progressive decline in brain function. There are more than 100 different types of dementia and the symptoms can vary not only with the type but also with the individual person. The most common symptoms are loss of memory, particularly short-term memory, problems with speech and understanding, confusion and mood changes.

Numbers Affected

Dementia is an increasingly common condition which now (2016) affects around 850,000 people in the UK and this is expected to double over the next 30 years. Globally numbers are predicted to have trebled by 2050 to 115 million. Although it can affect younger people – currently over 40,000 in the UK – it is found mainly in those over the age of 65 and the likelihood of developing it becomes greater with advancing age. One in three people over 65 today will die with dementia – more than half with Alzheimers'. A significant factor in the growth in numbers, therefore, is the steady increase in life expectancy. However, increasing numbers of cases of early onset dementia are being identified.

Types of Dementia

Alzheimer's Disease is the most common form of dementia, affecting some 490,000 people in the UK, slightly more women than men. In fact, dementia is now the leading cause of death for women. It is caused by brain cells dying due to small deposits of protein, known as 'plaques', developing between the cells and twisted strands of protein, 'tangles', developing within the cells. Its name is from the German neurologist who first identified them in 1906, Alois Alzheimer (1864–1915). No single cause of the disease has been found. In the 1960s it was suggested that ingestion of aluminium was an important factor but there has been no definitive proof of this and it is now thought more likely to arise from a combination of factors including lifestyle and general health. Even lack of sleep may play a role. A specific part of the brain where Alzheimers' develops has now been located. Low levels of Vitamin D can double the risk.

The disease may be present for up to 20 years before any symptoms appear and the first sign is likely to be memory problems, identified at this stage as mild cognitive impairment (MCI), although it is important to note that not all cases of MCI develop Alzheimer's. Other symptoms which gradually appear and become more severe over a period of seven to ten years include: language difficulties when speaking, problems carrying out everyday activities, confusion and mood swings. There can also be problems in recognizing familiar places and therefore getting lost close to home.

Although there is no cure for the disease, its progress can be slowed temporarily by drug treatment, in particular by drugs which maintain the supply of the chemical acetylcholine, of which there is a shortage in those with Alzheimer's. A blood test to identify Alzheimers' before the worst symptoms develop is very close.

Vascular Dementia is the second most common form of dementia and affects more men than women. It is caused by damage to the vascular system (blood vessels) within the brain, resulting in an insufficient supply of blood to the cells, which are therefore deprived of oxygen and eventually die. There are two main types: one arising from single or multiple strokes, the other from damage to small blood vessels deep within the brain. A third type, mixed dementia, is when Alzheimer's disease is also present. Many symptoms are similar to those for Alzheimer's, but can also include epileptic seizures and a 'stepped' deterioration. The conditions which can lead to vascular damage include high blood pressure, heart problems, high cholesterol and diabetes, and although the damage cannot be reversed, treatment of any underlying conditions may prevent further damage and thereby slow the progression of the disease.

Dementia with Lewy Bodies (*LBD*) account for 15% of dementia cases in older people and affects men and women equally. Lewy bodies are tiny spherical protein deposits that develop inside nerve cells in the brain, disrupting the brain's chemical messengers and leading to the degeneration and eventual death of the nerve cells. They are named after Frederic Lewy (1885–1950) who first discovered them in 1912. Why these bodies occur is not yet fully understood. Symptoms specific to LBD include hallucinations, a tendency to fall asleep during the day but have disturbed nights, fainting, falling, and a rapid fluctuation in abilities. It is closely associated with Parkinson's disease, whose sufferers often develop this form of dementia; conversely, at least half of those affected by LBD develop Parkinson's symptoms — slowness, trembling of the limbs, a shuffling walk, loss of facial expression, and changes in the voice. In the later stages of the disease the symptoms are similar to those of Alzheimer's disease. There is no cure but symptoms may be alleviated by certain drugs.

Fronto-Temporal Dementia is a rare type of dementia that usually develops in people under the age of 65 and is caused by damage to the frontal lobe and/or the temporal parts of the brain, the areas responsible for behaviour, emotion and language. The damage may be due to degeneration of the frontal lobe, to motor neurone disease or to Pick's disease, a disease caused by a particular type of protein deposit, a 'Pick body' as discovered by Arnold Pick (1851–1924) in 1892. In up to a half of cases the disease has been inherited, due to defective genes, but where it is not inherited the cause is unknown. The initial symptoms are changes in personality and behaviour, which may show as loss of inhibitions, lack of empathy with others and aggression. There may also be language difficulties and changes in eating habits but memory is initially unaffected. In the later stages, which can occur rapidly or after up to ten years, the symptoms are similar to those for Alzheimer's disease. There is no cure nor can its progress be slowed, and drugs used for Alzheimer's may make the symptoms worse.

Other Causes of Dementia

There are many other rarer diseases that may lead to dementia. *Korsakoff's syndrome* is caused by a lack of thiamine (vitamin B1) in the brain, usually due to heavy alcohol consumption over a long period, and its main symptom is loss of memory. It is named after a Russian psychiatrist specialising in alcohol-related disorders, Sergei Korsakoff (1853–1900), who first recognised its cause.

Treatment is total abstinence from alcohol, a healthy diet and vitamin supplements, which will halt the disease's progress and in some cases effect a complete recovery. *Dementia pugilistica,* commonly known as punch-drunk syndrome, is a decline in mental and physical abilities due to injury to the brain from multiple blows to the head. *Creutzfeldt-Jakob disease (CJD)* and its variant, *BSE (mad cow disease)*, causes dementia by the accumulation in the brain of abnormal prion proteins.

Reducing the Risk

There is no course of action that can guarantee that a person will not develop some form of dementia, particularly once over the age of 80 when one in five people are affected. However by following the general recommendations for a healthy life the risk of developing the most common types can be greatly reduced. The main risk factors for dementia are: smoking, high blood pressure, high cholesterol, obesity, and excessive alcohol consumption. So the risk can be reduced by not smoking, following a

Mediterranean-style diet, taking regular physical exercise and drinking, if at all, in moderation (in fact it is thought that a glass of red wine a day may help to protect against dementia). Continuing to use the brain in new ways, such as learning a language or learning to play a musical instrument, is also helpful, but it is thought that physical exercise, which improves the circulation of blood to the brain, and an active social life are even more important. In this respect, activities such as dancing or singing in a choir may be the ideal activities to combat dementia.

EAR PROBLEMS

The Ear.

This is not merely the outer portion which is visible to all of us—this part of the ear performs the sole function of collecting the sounds and leading them into a tube which consists of three parts: the outer part (which is the part in which the main troubles are collection of wax, small boils, and sometimes skin irritation); the middle ear, which is separated from the outer ear by a membrane, the ear-drum, and the main disorder of which is otitis media, due to infection; lastly, the inner ear, where the sound impulses, transmitted by a chain of tiny bones through the middle ear, reach the nerve which passes them to the brain.

Wax, or Cerumen, is naturally secreted in the ear, but in most cases will dry up and fall out. Some unfortunate people, however, tend to accumulate it, so that after varying periods of time the ear is completely blocked and deafness occurs. Then they have to go to the doctor to have it syringed. There is no cure for this tendency except periodic syringing, although there is an oil on the market which usually softens the wax and makes it come away of itself. *Boils* in this part of the ear are small but rather painful; they should be entrusted to the doctor, who will give something to relieve the pain. However, once the boil has started, it is unlikely to regress, and will probably come to a head and burst, with consequent relief to the patient. Whilst we are dealing with the outer ear it should be said that, like the eyes, it should not be interfered with except by someone who knows something about it. Mothers should not poke the corners of towels into the ear in an attempt to clean it, nor if, as frequently happens, a child puts a bead or a pea into the ear should they try to dig it out. This should be left to the doctor.

Otitis Media, or infection of the middle ear, is another cause of earache, and, since the middle ear is shut off by the ear-drum from contact with the outside world, the ordinary source of infection is from the throat by way of the Eustachian tube, a narrow tube which passes between the back of the throat and the middle ear. Its normal function is to equalise pressure between the middle ear and the atmosphere—that is why, for example, when a large gun is being fired, soldiers are told to keep their mouths open, otherwise their ear-drums might be burst. But not only air but germs can pass up the tube, and when infection exists in the throat (such as adenoids or tonsillitis) it may move up the middle ear and start disease. When this happens, pus begins to form and accumulates until it presses against the ear-drum, which causes severe pain. Without treatment one of two things may then happen: either the ear-drum bursts or the infection may spread backwards into the mastoid area, an area of spongy bone immediately behind the ear. This is known as *mastoiditis*, and together with otitis media, can be dealt with only by a skilled doctor. Sometimes antibiotics are adequate, but in other cases operation is necessary.

Tinnitus is the medical term for noises in the ears, which is one of the commonest conditions met with in the doctor's surgery. There are numerous physical causes, but there can be little doubt that very many of the cases seen are neurotic and show no physical disorder at all. Some of these unfortunate people, who undoubtedly suffer a great deal, go around from one doctor to another seeking relief and failing to find it, because the trouble is so often in their minds rather than their ears. One of the physical causes of tinnitus is *otosclerosis*, a disease of the inner ear in which the tissues become hardened and increasing deafness results. It is now known that tinnitus arises when hairs in the inner ear are damaged and the brain responds by trying to amplify sounds. One treatment is the operation of fenestration or its more recent modifications such as stapedectomy which give good results. Researchers are now working on the possibility of drug treatment by 2020. At present, one in ten people in the UK is affected by everyday tinnitus.

KEYHOLE SURGERY

One of the most fundamental of medical ethics is not to harm the patient. In the field of surgery this can be loosely translated as "do not make holes any bigger than necessary." Although surgeons have always tried to follow this, they have only been able to do so to any great extent since the 1980s and improvements in keyhold surgery have followed the development of fibre-optics. Methods for examining the inside of the body using rigid tubes with mirrors to guide light have been available for many years, but were applicable only to parts of the body which can be reached from the surface in a straight line. Fibre-optic systems allow light to be passed down a flexible bundle of fibres, and this has enormously widened the range of body parts that can be examined for diagnostic purposes. The surgeon can, for example, pass an endoscope down past the vocal cords into the lungs; by bending the flexible tip of the endoscope, he can guide the instrument into even very small bronchial branches, to look for cancers and other lesions.

Endoscopes were taken another step forward with the development of tiny surgical instruments—scissors, diathermy probes and the like—with which small samples of tissue (biopsies) could be removed and brought back out of the body for more detailed examination.

The Advantages of Keyhole Surgery

One major advantage of keyhole surgery is that the reduction in the level of invasiveness needed to treat a condition is dramatically reduced, so that patients have to stay in hospital for only a fraction of the time that would be needed using earlier methods. Keyhole surgery forms an important part of the treatment of coronary sclerosis, where the arteries providing blood to the heart become blocked by the build-up of atheroma. Coronary bypass surgery used to be the "standard" treatment for this condition, and represented major surgery.

The keyhole method consists of passing a catheter from the surface of the body into an artery and guiding it into the blockage under the control of X-ray monitoring. A small balloon at the tip of the catheter is then inflated, which opens up the narrowed artery and restores the flow of blood through it, reducing the severity of angina pectoris.

Uses of Keyhole Surgery

Investigation of gastro-intestinal diseases often used to need a major operation, laparotomy. In many cases it is now standard practice to put an endoscope through a tiny incision in the abdominal wall and guide it to the damage for examination and sample collection and, in some cases, repair. Endoscopes can also be passed into the intestines for examination and treatment without any incision at all.

Hysterectomy, another procedure that in the past required laparotomy, is now routinely performed using miniaturised instruments passed into the uterus through the vagina, which reduces hospital in-patient from 10 nights often to only one night. Prostate hypertrophy, in which the prostate gland in men swell ups and blocks the passage of urine, is now treated by tiny instruments passed through the penis, in a procedure known as transurethral prostatectomy. Joint diseases and traumas are often examined and treated by similar methods. Many sportsmen with knee injuries will be familiar with the arthroscope.

Alternative Non-Invasive Surgery

These examples show that keyhole surgery is a form of non-invasive surgery. Other ways of achieving the same effect include the use of focused ultrasonic sound waves to break up kidney stones (lithotrypsy) instead of major abdominal surgery; breast lumps can often be removed by minor procedures guided by extremely accurate X-ray equipment in place of the older lumpectomy and mastectomy approaches. As the application of engineering to surgery spreads, so does keyhole surgery.

MEDICAL NEWS AND NOTES

PET Scans

Positron emission tomography (PET) scans are a recent refinement of the technique of injecting a radioactive marker to study disease. New markers have been developed to measure processes such as glucose metabolism. This makes them particularly useful for examining a range of different cancers, and they may show the spread of cancer much earlier than other tests. They can also help accurately target treatments such as radiation therapy. In future, they may give an idea of response to treatments like chemotherapy, long before the results would otherwise be known.

These tests are not only more sensitive and accurate but often also easier on patients.

Blood Groups

Human blood plasma contains factors which clump, or agglutinate, the red cells of some other people's blood. The main blood groups are called A, B, AB, and O. The plasma of group A blood contains an anti-B factor and *vice versa*, so that people of groups A and B cannot accept each other's blood. Group AB contains neither anti-A nor anti-B factor and people with this group can therefore receive transfusions from both but can give to neither. Group O contains both anti-A and anti-B, and can therefore receive blood only from group O but can donate blood to all groups. It is important that transfused cells should not be agglutinated by the factors in the recipient's plasma. Apart from the so-called ABO system, there are several other blood groupings, one of which is mentioned under **Rhesus Factor.**

Rhesus Factor

Apart from the ABO blood group system (*see above*) there is another blood group system (designated the Rh- system or Rhesus system). Everybody is either Rh-positive or Rh-negative. Three positive factors (denoted C, D, E) and three negative factors (denoted c, d, e) are involved. This system of blood factors is inherited separately from the ABO group, so that one may be A Rh+ or A Rh−, *etc.* Both the positive and the negative factors are antigenic, *i.e.*, if introduced into other blood they will stimulate the production of substances which act in some way against the cells introduced.

Blood Donors

The need for people to give blood has probably never been greater. It is one of the most useful tasks people can do—it only takes about an hour of your time (and the donor hardly feels a thing!) Hospitals need the equivalent of 10,000 blood donations every day. Blood is used not just in accidents and emergencies but in the treatment of cancer and burns, in childbirth, heart surgery and organ transplantation.

Although most people can give blood, only 5% of those who can actually do. Anyone who is not yet a blood donor could start today as long as they are aged between 17 and 59, generally in good health and weigh at least 7st 12lbs (50kg). Existing donors can give blood until they reach 70—ideally three times a year.

For more information readers can contact 0845 7711711 or visit www.blood.co.uk.

Mouth Cancer (Oral Cancer)

A new awareness programme to highlight the spread of mouth cancer was launched back in 2005. With around 8,000 new cases annually in the UK, and over 1,700 deaths, cancer of the lips, tongue, cheek, vocal chords and throat has now become more frequent. The mouth should be examined regularly to check for warning signs such as ulcers that do not heal or red and white patches.

Once considered mainly a disease of men over 50, it now affects more younger men (and the number of women with the disease has risen by a third since 1995). Excess alcohol intake, as well as smoking, are being blamed. Those carrying the HPV virus are also at risk.

Survival rates are very good if the disease is caught early.

Frozen Shoulder

An extremely painful and stiff condition of the shoulder in which movement is very much restricted, even "frozen" altogether. Despite the use of painkillers, in severe cases the condition may last 2 or even 3 years. Pain is worse at night, with sleep often badly disrupted. It is thought to be caused by scar-like tissue forming. For reasons not yet understood, diabetics are more liable to this condition.

Abdominal Aortic Aneurysm (AAA) Screening

AAA screening is a simple ultrasound test which the NHS is offering free of charge to all men in the year they turn 65. The aorta is the main blood vessel that supplies blood to your body. Large aneurysms are rare but can be very serious. As the wall of the aorta stretches it becomes weaker and could give way. If this happens, the person usually dies.

An aorta which is only slightly larger than normal is not dangerous. However, it is still important to know about it so that doctors can monitor the aneurysm to see if it gets bigger. The easist way to find out if you have an aneurysm is to have an ultrasound scan of your abdomen.

Men are six times more likely to have this type of aneurysm than women. The chance of having an aneurysm increases with age.

The Zika Epidemic

The Zika virus was first isolated back in 1947 from a rhesus macaque in the Zika forest of Uganda. The virus is spread by a mosquito, the *Aedes aegypti*, which also carries such other viruses as dengue and yellow fever (*see* **Z11**) and also chikungunya (*see* **Z62**). In May 2015, an outbreak of the disease was reported in Brazil. By early 2016, more than 1·5 million Brazilians had become infected and it had spread to the other countries in South America and the Caribbean. It was set to become a global emergency.

In many cases, symptoms (where they appear) resemble those of the flu and are rarely life threatening. Crucially, however, the Zika virus is linked to birth defects in pregnant women. A child may be born with a smaller head (*microcephaly*) and underdeveloped brain. Hence the Zika virus has become an urgent medical emergency.

If you have to travel in an area where the *Aedes aegypti* mosquito is found, take every precaution to avoid being bitten. Wear long sleeves, long trousers tucked into socks and at night use insect screens, air conditioning *etc.* Also, take up-to-date medical advice.

PART IV. GLOSSARY

Abdominal aortic aneuryisms, name for the insidious ballooning of the main blood vessel in the abdomen. Around 10,000 people die annually in the UK when rupturing occurs. Screening can reveal those at risk (*See* **Z61**).

Acoustic Neuromas, benign tumours of the acoustic nerve. They can cause deafness. A link has been noted suggesting they are more common in mobile phone users.

Adenoids, the overgrowth of glandular tissue in the back of the throat. Often caused by infection they usually disappear by the age of 10 .

ADHD (**Attention Deficit Hyperactivity Disorder**) is a condition affecting some youngsters. Its symptoms of restlessness, forgetfulness and lack of attention (once blamed on bad behaviour) may be linked to the brain chemical dopamine. Sometimes just called ADD (Attention Deficit Disorder). Around half of sufferers find symptoms continue into adult life. A tiny genetic fault is responsible.

Alternative Medicine. *See* **J3**.

AMD. Age-related macular degeneration.

Amniocentesis, a pre-natal test in which a needle is used to extract amniotic fluid.

Anabolic Steroids. Synthetic hormones which stimulate growth, muscle development and sex drive.

Anaesthetic. Any drug used to abolish pain during an operation.

Androgens. The hormones (*e.g.* testosterone) responsible for male characteristics.

Ankylosing Spondylitis (AS). A painful progressive rheumatic disease, mainly but not always of the spine. There is a gradual onset of back pain and stiffness.

Ankylosis. Partial or complete fixation of a joint as after some types of arthritis. In other cases deliberately produced by surgery.

Antibiotics, a collective name for any substance derived from micro-organisms or fungi which is capable of destroying infections. *See* **Z4**.

Antihistamines. Medicines used to treat allergies such as hay fever and rhinitis.

Aphasia. A form of brain damage affecting language.

Arrythmia. Irregular pulse rhythms of the heart.

Avian Flu. *See* **Bird Flu** (*below*).

Barium meal. Barium sulphate is opaque to X-rays and before X-ray pictures of the alimentary canal radiologists give a "barium meal" to the patient so that the alimentary canal shows up more clearly. Barium X-rays can reveal bowel diseases.

Bird Flu (**Avian Flu**), typical flu-like symptoms, eye infections, pneumonia and respiratory disease contracted from birds, chickens *etc.* in Asia. In 2011 a vaccine-resistant strain appeared in Asia. In 2013 the H7N9 virus emerged in China.

Blood Groups. *See* **Z61**.

Cachexia. Extreme wasting due to disease.

Caesarean operation. When the abdomen has to be opened to remove the child.

Carbohydrates. The scientific name for sugars, starches and cellulose, *See* **Z34(1)**, **Z39–40**.

Carcinogen. Any substance which causes cancer.

Cellulitis, inflammation of body tissue, most often below the surface of the skin. It is treated with antibiotics.

Chikungunya, a virus found in the Caribbean. Spread by mosquitoes, it causes fever, rashes and severe joint pain.

Chlamydia, the most common sexually-transmitted infection in Britain. It can lead to pelvic inflammatory disease and infertility. In the UK, one in eight teenage girls has chlamydia. Around 200,000 people test positive each year in the UK. The condition threatens not only female fertility but can make men infertile by damaging their sperm quality. A vaccine is now being developed in America. The signs and symptoms are invisible. Check out www.chlamydiascreening.nhs.uk

Chronic. A chronic disease is one which is prolonged and relatively mild, as opposed to an acute one which is short and severe.

Chronic Fatigue Syndrome. An alternative name for ME (Myalgic Encephalomyelitis). *See* **Z63**.

Claustrophobia. A physical symptom, which causes the individual to be afraid of enclosed spaces. *See under* **Obsessional neurosis, Z51(1)**.

Clostridium difficile (abbreviated to **C.diff**), a hospital bug causing a severe form of infectious diarrhoea. The number of hospital deaths from this bacterial infection has recently soared. The disease first originated in Montreal, Canada.

Coccyx. The end of the spinal column.

Coeliac Disease. A flattening of the inside of the intestine caused by gluten, the protein found in wheat, rye and barley. Symptoms include abdominal pain, weight loss and poor absorption of nutrients. It is more common in women than men, and is becoming more frequently found in children. More gluten-free foods are now being promoted.

Cortisone. A hormone produced by the adrenal glands. *See* **Z43(1)**.

Cot Deaths (properly **Sudden Infant Death Syndrome**). The primary cause of death in babies more than one month old. This very distressing and inexplicable loss of life could be due to defective genes – involving lung function, the immune system *etc.* However, recent research suggests an imbalance of the brain-signalling chemical serotonin could be a factor.

Cryoblation, the freezing of tissue. An increasingly common treatment for corns, warts and also cancer of the kidney, prostate and skin.

Cryosurgery, a pioneering treatment for cancer which destroys tumours by freezing them.

Down's Syndrome, a genetic condition caused by the presence of an extra chromosome—47 instead of 46. Those affected have learning disabilities and difficulties in sitting, crawling and walking. Babies born to older mothers have a higher chance of having Down's syndrome. The NIPT test can detect Down's syndrome from the blood of pregnant women and has raised the prospect of routine screening for the condition for every expectant mother who wants it. About 1 in every 1,000 babies in Britain is born with Down's Syndrome, around 750 each year. Average life expectancy has risen from only 12 in the 1940s, to around 60 today. The new non-invasive pre-natal test (NIPT) could be a second-step in detecting Down's syndrome.

DRE. Digital Rectal Examination.

Dyslexia, a specific learning disability that can affect reading, writing, memory *etc.* It is hereditary and scientists have now discovered the gene responsible for it. New flashing light treatment is having positive results for many sufferers. There are 375,000 children in the UK with dyslexia. Readers may wish to contact www.dyslexiaaction.org.uk

Dysphagia is the term for difficulty in swallowing.

Dyspraxia, a developmental disorder in which the organisation and sequencing of movement is impaired. Boys are four times more likely to be affected than girls. The Dyspraxia Foundation helpline is 01462 454986.

Dystonia A condition in which there is abnormal muscle rigidity, fixed postures and painful spasms.

Ebola Virus Disease (**EVD**) is a severe and frequently fatal disease, easily spread through contact with the bodily fluids of a person. There is intense weakness, cold, vomiting and diarrhoea, sometimes with internal and external bleeding. It first appeared in Africa in 1976. The worst outbreak yet started in West Africa in 2014. An effective vaccine is now very close.

Economy Class Syndrome is deep vein thrombosis (*see* **Z30**)—a clot in the veins deep in the leg ("deep vein thrombosis") which travels via the bloodstream to the lungs ("pulmonary embolism"). Periods of immobility, such as during long flights, predispose to its development.

Ecstasy ("e" or MDMA) is an illicit drug that stops brain cells from reclaiming a chemical used to signal between cells (*see* **Z46**). This leaves the signal from these cells switched on resulting in an emotional high and a feeling of closeness to others. Users often take it before all night dancing. It occasionally causes an uncontrolled rise in body temperature (hyperthermia) which may be fatal, and may cause depression.

ECG. Electrocardiagram.

ECT. The abbreviated form of the name for a modern type of treatment for certain psychiatric disorders—electro-convulsive-therapy. *See under* **Psychosis, Z50**(1).

Empyema. A collection of pus in the lung (usually a complication of other diseases).

Endemic. Referring to a disease, means prevalent in a particular area.

Endocarditis. Disease of the valves of the heart, *See* **Z29**(**2**).

Endometriosis, a condition producing pelvic pain in which the endometrial cells lining the uterus start to flourish elsewhere in the body. Diagnosis often takes far too long. It affects 2 million women in the UK, but some doctors are reluctant to provide medication.

Epidermolysis Bullosa (**EB**). A painful genetic skin blistering condition which makes skin excessively fragile.

Erysipelas. A skin rash infection also called St. Anthony's Fire.

Fibroids. Non-cancerous tumours that grow slowly within the muscular wall of the uterus. *See* **Z55**(**2**).

Foetal Alcohol Spectrum Disorder (**FASD**), the umbrella term for a variety of disorders caused by a mother drinking alcohol while pregnant.

Ganglion. A small cystic swelling, usually on the wrist, dealt with by simple surgical treatment.

Gastritis. Inflammation of the stomach.

Gastroscopy. A test to look at the lining of your oesophagus (gullet), stomach and duodenum. The examination is carried out using a thin, flexible telescope called an endoscope or gastroscope. The telescope is about the diameter of a pen.

Genetic Targeting. Prescribing drugs according to a person's genetic profile.

Geriatrics. The medical study of old age.

Gilomas. The most common form of brain tumour.

Gingivitis. Inflammation of the gums due to infection and requiring treatment by a dentist. The classic sign is red, swollen gums which bleed on brushing.

Haemoglobin. The red pigment in the blood.

Halitosis, the correct term for bad breath. Often caused by a problem in the mouth (*e.g.* gum disease or bacteria).

Hallucinogen, a drug which acts upon the brain to create sensory illusions or hallucinations with a variety of emotional effects. One of the most widely studied is LSD (*q.v.*) which will produce symptoms very similar to those found in some mental disorders.

Heller's Syndrome, condition similar to autism (**Z51**).

Heterochromia, the condition in which a person has different coloured eyes (around 1% of people are affected).

HPV (**Human Papilloma Virus**), a virus now known to be present in cases of cervical cancer. Girls aged 12–17 should be vaccinated to protect them. Boys also are at risk.

Huntington's Chorea, a neurological disease which manifests itself between the ages of 35 and 55. This degenerative condition damages nerve cells in the brain, affecting movement, thinking and behaviour. Far more prevalent than once thought, it is genetically inherited. A drug to reverse the effects is undergoing trials.

Hyperemesis gravidarum. A severe form of morning sickness in pregnancy. Medical treatment involves the use of prochlorperazine, an anti-sickness drug.

Hypno-Anaesthesia, the use of medical hypnosis to overcome pain in place of anaesthetic drugs.

Hypochondriasis, the unfounded belief that one is suffering from a serious disease.

IBD. Inflammatory bowel disorder.

IBS. Irritable Bowel Disease. This includes Ulcerative Colitis and Crohn's Disease. Symptoms may include bloating, constipation and abdominal discomfort. The condition can sometimes be relieved by antibiotics.

Insulin is a hormone which controls the supply of sugar from the blood to muscles. The breakdown of sugar provides energy. In diabetes there is a lack of insulin, causing a build-up of blood sugar which can be released by the injection of insulin. It is secreted by the islet tissue of the pancreas, from which it was isolated in 1922 by Banting and Best. In 1980 insulin became the first product of genetic engineering techniques to reach clinical trials.

Interferon, identified in 1957 as a defence protein produced in animal cells, is also produced in human immune systems. Its use as a possible anti-cancer agent as well as for other complaints has been limited by extraction problems. Modern production is likely to be by genetic engineering. In 1980 the amino acid sequence was determined for the 150 residues in human interferon.

Laryngitis. Inflammation of the vocal chords, causing hoarseness, loss of voice and sore throat. The singer's nightmare!

LDL (**Low-Density Lipoproteins**), term for the "bad" type of cholesterol.

Legionnaire's Disease, caused by the Legionella bacterium. Very serious outbreaks (as at Stafford hospital in 1985 when 28 people died) can occur. Sometimes the bacterium is found in recirculating and hot-water systems. A recent outbreak was in Edinburgh in 2012.

Lipoedema. The abnormal build-up of fat cells in the lower half of the body.

LSD (d-lysergic acid diethylamide). An hallucinogenic drug which has provoked much debate. It is active in extremely small quantities and a dose as small as a fifty-millionth part of a gram can cause marked disturbances of the mental function in man. LSD has been used in the study of mental disease because it produces symptoms very similar to mental disorders such as schizophrenia.

Lupus. Disease more prevalent in black people (especially women) which causes the patient's immune system to attack his or her own body tissues. *Lupus: A Guide for Patients* by Graham R V Hughes, £3 including postage is available from Lupus UK, St. James House, Eastern Road, Romford, Essex, RM1 3NH.

Lyme Disease. A virus, spread by ticks, which attacks the nervous system.

Magnetic Resonance Imaging (**MRI**), a technique for diagnosis based on the emission from the body of electro-magnetic waves. The patient is exposed to radiofrequency radiation. The technique avoids using X-rays.

ME (**Myalgic Encephalomyelitis**), chronic fatigue syndrome with symptoms of extreme physical or mental exhaustion and muscular pain. Now called Chronic Fatigue Syndrome (CFS). Severe sufferers have to rely on bed rest, but anti-depressants, nutritional guidance and alternative therapies may be beneficial. The cause may be psychological but there is increasing evidence of a biological factor. Once called neurasthenia.

MERS (**Middle East Respiratory Syndrome**). A similar virus to SARS (*q.v.*). MERS emerged in Saudi Arabia in 2012. Isolated cases have been found as far away as South Korea.

Mesothelioma, an untreatable cancer of the membrane that lines the chest and abdomen. Exposure to asbestos has led to thousands of cases.

Minamata Disease. A neurological disease caused by mercury poisoning.

MMR, a vaccination which immunises against measles, mumps and rubella (German measles). An unfounded scare that the jab increased the risk of autism has led to major outbreaks of measles in recent years.

MRSA (**Methicillin Resistant Staphylococcus Aureus**), a bacteria resistant to almost all antibiotics. An alarming increase in annual cases of MRSA is now recorded. Hospital-acquired infections (nearly half drug resistant) are a cause of serious concern. A new drug to attack MRSA was announced in May 2008.

Myeloma. A cancer of the bone marrow in which large amounts of paraprotein are produced. The outlook for patients is poor.

Narcotic, is a drug that produces stupor; complete insensibility or sleep. In terms of drug addiction, it has been defined as altering the user's perception of himself and of the external world, being taken primarily for that purpose.

Olfactory. To do with the sense of smell.

Oncology. The study of tumours.

Opium was known in the ancient world, and used by them as a medicine. It is obtained from the poppy flower (*Papaver somniferum*), the unripe "head" or seed capsule of that flower yielding a juice which when dried becomes the opium of commerce. The poppy is cultivated for the sake of this juice, which yields various alkaloids, such as morphine, narcotine, codeine, *etc*. These days the drug is rarely used medicinally.

Ostectomy. The surgical removal of a bone (or part of).

Paediatrics. The study of the diseases of children.

Paget's Disease, a severe bone disease. Symptoms may include curvature of the spine, bowing of the legs *etc*.

Painter's Colic. Intense intestinal pain caused by lead poisoning.

Penicillin. An antibiotic drug produced by the mould *Penicillium notatum*, and discovered by Sir Alexander Fleming in 1928. It is one of the most effective chemotherapeutic agents known. The mould produces a number of penicillins, all of which are effective antibiotics.

Peridontal Disease, inflammation of the tissues which support teeth and attach them to the jaw. **Gingivitis** (*q.v.*) is the term used when inflammation only involves the soft gum. **Periodontitis** is where inflammation reaches the underlying bone.

Pharmaco-genetics. The new science of diagnosing diseases with reference to a person's genetic profile.

Pharmacopoeia, an official publication containing information on the recognised drugs used in medicine. Each country has its own pharmacopoeia. The British Pharmacopoeia (BP) is published under the direction of the General Medical Council. The Pharmaceutical Society issues the British Pharmaceutical Codex (BPC); there is also an International Pharmacopoeia (2 vols.), issued by the World Health Organisation.

Phlebotomy. The letting or taking of blood in the diagnosis and treatment of a disease.

Placebo, medical treatment that the therapist uses deliberately although he knows it is without any specific effect on the condition being treated. There may be various medical reasons for using placebos, *e.g.*, for the beneficial psychological effect on people who like to feel something is being done for them; for differentiating during clinical trials of a new treatment between those persons given the real thing and those given a placebo or inactive imitation.

Plantar fasciitis, a painful inflammation of the tissues of the foot. Sometimes called 'Jogger's Heel'.

Plaque. In dentistry, the film of bacteria which constantly forms on all teeth, leading to tooth decay (dental caries) and peridontal disease (*see above*).

Pneumococcal disease, is the term used to describe a range of illnesses such as pneumonia, septicaemia (blood poisoning) and meningitis (inflammation around the brain), when these are caused by the bacterium *Streptococcus pneumoniae*.

Post-Natal Depression, (now often referred to as "PND") means becoming depressed after having a baby. Sometimes this is easy to explain – the baby is unwanted or abnormal. Mostly, though, the depression makes no obvious sense; but it is one of the most common complications of childbirth.

Postpartum Psychosis. A severe mental illness triggered by childbirth found in one in every 500 mothers. Symptoms include extreme high or low moods, delusions and paranoia. It is classified as a psychiatric emergency.

Pre-eclampsia, a disorder causing high blood pressure among pregnant women. It affects one in 25 pregnant women. In some cases it can be life-threatening to both mother and baby. A new test detects changes in the blood that can mean the placenta is not developing properly.

Progressive Supranuclear Palsy (**PSP**), a neuro-degenerative disease which affects the brain stem. It was identified as a separate disease in the 1960s. The cause is not yet known and there is at present no cure.

Prostate Specific Antigen (**PSA**), the chemical 'signature' of an abnormal prostate gland.

Proton beam therapy, a type of radiotherapy which uses a precision high-energy beam of particles to destroy cancer cells. It has certain advantages because it can be controlled by a measure of millimetres.

Psychosomatic diseases. Psychosomatic diseases are those physical ailments due to emotional causes. They include such complaints as high blood-pressure, gastric ulcer *etc*.

Pyorrhoea. An infection of the gums which causes the edges of the tooth sockets to bleed easily when the teeth are being brushed.

Quinine, a vegetable alkaloid obtained from the bark of several trees of the *Cinchona* genus. It is colourless and extremely bitter. The drug, sulphate of quinine, is one of the most valuable medicines, forming a powerful tonic. It is anti-periodic, antipyretic and antineuralgic. In cases of malaria it is the most efficacious remedy of natural origin known.

Radical prostatectomy. An operation to remove the whole prostate gland. Used to treat prostate cancer that is contained within the prostate gland.

Radiotherapy. Any treatment using radioactive particles or high energy rays to destroy tumours or other cancerous cells.

Rhesus Factor. *See* **Z61.**

Rods and Cones are cells in the retina of the eye which convert light into nervous impulses which can be interpreted by the brain.

RSI (**Repetitive Strain Injury**), an injury most prevalent among computer users and factory workers. It may begin with a minor ache before eventually becoming a persistent pain. Symptoms include pain in the hands, elbow, wrist or shoulder. Around 450,000 British workers now suffer these upper limb problems.

Salpingitis, infection of the Fallopian tubes. *See* **Z55**(**1**).

SARS (**Severe Acute Respiratory Syndrome**), a deadly flu-like virus which spread rapidly from south China and Hong Kong in 2003. Its main symptoms include fever above 38°C, breathing difficulties, low blood oxygen and a dry cough. A new type of coronavirus (MERS) was detected in 2012. Both SARS and MERS are believed to have originated in wild animals.

Sciatica, painful affliction radiating along the sciatic nerve, extending from the buttocks down the back of the leg to the foot.

Screening is looking for a disease in the absence of symptoms. It may be extremely effective such as for cervical cancer, which can be detected and treated many years before it would otherwise be found. Screening for prostate cancer is controversial, because some men may have treatment for an illness that might not otherwise harm them.

Sickle-cell disease, a hereditary blood disease characterised by the production of an abnormal type of haemaglobin. This painful disease mainly affects people of African descent (but can be found also in the Middle East and India).

Sudden Infant Death Syndrome. *See* **Cot Deaths.**

Swine Flu. A human variant of swine fever, a respiratory disease affecting pigs. Symptoms are flu-like, including fever, aching body, nausea, sore throat, vomiting and/or diarrhoea. It is spread by coughing, sneezing and touching. H1N1 penetrates deeper into the lungs and can inflict more damage than common seasonal flu. Around 275,000 people (15 times the number first estimated) may have died.

Temperature. The body temperature is regulated by a small area at the base of the brain. Normally it should be about 37°C. *See* **Z9**(**1**).

Thalassaemia. A little known but potentially fatal hereditary blood disorder. Around 75 % of babies with this disease are born to Asian parents. New scanning techniques are reducing mortality rates.

TIA (**Transient Ischaemic Attack**). A mini-stroke.

Tourette's Syndrome, a neurological disorder that causes involuntary facial, vocal and muscular tics. The genetic mutation that causes it has now been identified. Named after the French neurologist George Gilles de la Tourette. It is three times more common in men than women.

Trachoma, the world's most common cause of preventable blindness. There are *c.* 320 million people at risk worldwide. It is excruciatingly painful, causing the eyelids to turn inwards.

Viagra, a drug (in the form of a little blue tablet) which counters impotence in men. Demand for sildenafil (which is sold as Viagra) and other erectile dysfunction drugs is rising. A "female Viagra" (flibanserin) has now been developed.

Virotherapy. A new way to tackle cancer cells by the use of viral infections (which are known to eliminate cancer cells). Clinical trials are now underway.

Vitiligo, a common skin condition (affecting 1 in every hundred children and adults) which causes white patches where the skin has lost its pigmentation).

West Nile Disease. A disease spread by mosquitoes which have fed on infected birds. It can be fatal, causing inflammation of the brain and spinal cord. Many people only experience much milder symptoms. There is no vaccine and the disease has now spread to nearly all parts of the world.

Zoonoses, diseases that originate in animals but spread to humans. Their numbers are increasing as animals are driven closer to populated areas.

SUBJECT INDEX

Each section has a letter and, where appropriate, the column is given in brackets after the page number, *e.g.*, T8(1), C20(1). Some of the sections are alphabetically arranged and index themselves. In addition "The World of Music" has a separate index of composers and also a glossary. For historical terms, *see* **Section E** and for biographical entries *see* **Section B**.

THE STORY OF PEARS

1897-2017

The origins of *Pears Cyclopaedia* are no less fascinating than its phenomenal success – a success which produced sales of 3 million copies by the 1930s and at least as many again since. That success dates to 1865, when a young man of 24 joined the business of A&F Pears Ltd, soap makers to Queen Victoria. At a well-known Academy of Dancing and Deportment in the West End, Thomas J Barratt made the acquaintance of the eldest daughter of Mr Francis Pears. Miss Pears became Mrs Barratt and Mr Barratt became the London Manager of Pears!

Thomas Barratt was an advertising genius. He declared that he would advertise as no soapmaker had ever advertised before. In the then relatively new profession of advertising, he made Pears Soap a world-wide name. Such advertisements as "Bubbles" and "Two years ago I used your soap, since when I have used no other" achieved lasting fame.

But perhaps the most original advertisement of all for Pears Soap was the little red *Pears Shilling Cyclopaedia*, first printed for A&F Pears by David Bryce and Son of Glasgow. It was published in December 1897, the year of Queen Victoria's Diamond Jubilee. This first edition contained an English dictionary, a medical dictionary, a gazetteer and atlas, desk information and a compendium of general knowledge entitled "A Mass of Curious and Useful Information about Things that everyone Ought to know in Commerce, History, Science, Religion, Literature and other Topics of Ordinary Conversation".

The idea was to keep the general public informed on the issues of the day, to equip them for social discourse, satisfy their curiosity and widen their learning. Topics ranged from hard facts to questions of etiquette, from why the Russians needed a port on the Mediterranean to the longevity of the clergy!

Although *Pears Cyclopaedia* slipped its connections with soap back in 1960 when the publishing rights were acquired by Pelham Books (and in turn passed to Penguin Books), there has been astonishing editorial continuity (only two editors since 1946, only three in the first 50 years). Now the price is rather more than the original shilling, but *Pears* still represents remarkable value.

Many of the popular features of the early editions were retained. The medical section, the gazetteer, the sections on Science, Literature, Ideas and Beliefs, Historical Events and General Information all remained there. Also there were topics of current social and political interest, specially commissioned for each edition. There are newer, equally popular favourites in the present edition, including Classical Mythology, Sporting Records, the Biblical Glossary, Music and the World of Art. It is this blend of innovation and tradition – the tried and tested facts and figures alongside authoritative new articles in every edition that made *Pears* so popular with generation after generation.

The single most important factor in the *Pears* success story, and the key to its truly unique publishing phenomenon, is that *it is the only book of its kind to be fully revised and updated by a team of experts every year*.

Schools and colleges, offices and libraries, students and researchers, newspapers, radio and TV stations – for all these, and many more, for whom readily accessible, reliable facts at their fingertips are needed. *Pears Cyclopaedia* remained an invaluable companion. Now, the ready availability of electronic information has made the printed reference book no longer commercially competitive. That is progress. But many will miss the passing of a famous book, that in its heyday, had become not only a national institution but also the reliable pathway for successive generations of working-class families to a better education.
